As the members would frequently require to meet for the purposes of professional consultation, rooms would be set apart during a portion of the day for that purpose, and separate lockers would be provided for members using the consulting-rooms, where instruments, or apparatuses, &c., might be safely secured, so as to afford all the advantages an independent house could supply at a comparatively trifling cost. Of course the club would supply the ordinary conveniences of such a place of resort. It would possess a reading-room, refreshment-room, and library, &c. These are some of the advantages the promoters propose to accomplish by the establishment of the new club.

The movement has been carried on thus far without incurring any preliminary expenses beyond those necessary for printing, postage, and advertising. A favourable opportunity now offers of opening the club in the neighbourhood of Cavendish-square, and to enable the committee to carry out the necessary arrangements, it is important that gentlemen desirous of joining should send an early intimation of their intention of so doing either to a member of the committee, or to the Hon. Secretary.

The following resolutions were afterwards put to the meeting and adopted.

First—"That in the opinion of this meeting, it is desirable to establish a club in London for the social intercourse of members of the Medical Profession, British and foreign; to promote and maintain a mutual interest and fellowship between them, and to cultivate friendly relations with men of art, science, and letters."

Second—"That the club be called the Medical Club, but that it be competent to elect as members gentlemen connected with literature, science, and art, as well as members of other scientific societies. The election in all cases to be by ballot."

Third—"That a committee be formed, consisting of the following gentlemen, with power to add to their number, viz.—Sir W. Fergusson, Bart., London; Dr. Farquarson, Coldstream Guards; Mr. Clement, M.P., Shrewsbury; Mr. Probert, London; Dr. Bell Fletcher, Birmingham; Mr. Grigg, R.N., Greenwich Hospital; Sir Charles McGrigor, Bart., London—to settle the rules, to determine the amount of the future entrance and subscription, and to take the necessary steps for opening the club as soon as practicable, it being distinctly understood that, previous to their

adoption, the rules shall be revised by counsel, so that members shall not, under any circumstances, be rendered liable to pay more than the amount of their entrance fee and subscription."

Fourth—"That a copy of these resolutions be forwarded to the members of the club, with a request that they will circulate them among their friends."

The proceedings concluded with a vote of thanks to the Chairman, who, in acknowledging it, proposed a vote of thanks to their indefatigable Hon. Secretary, Dr. Lory Marsh, which was also carried by acclamation.

London Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 14, 1866.

THE VISITATION OF EXAMINATIONS.

ANOTHER Medical Session having now fully come into existence, and the attention of hundreds of Medical Students in the three divisions of the British Empire being necessarily fixed upon the ordeals which they must all undergo before they can receive their titles to practise, the efficiency of the different Examining Boards again becomes a question of absorbing interest; and while, perhaps, the minds of some of the aspirants are veering towards those quarters where they think Licences or Diplomas can be most easily procured, it is precisely to those very same quarters that the most jealous scrutiny of the senior and more thoughtful members of our body is directed. It is, in fact, egregiously unfair, especially now when all professional distinctions are levelled by the Medical Act, if the same Diplomas and Licences, which are procured only with great expense and difficulty at some places, should be obtainable on cheap and comparatively easy terms at others. The Medical Act has unquestionably done something to elevate the tone of the examinations in general; but it has hitherto been powerless to compel particular institutions wholly to accommodate their systems of education and examination to the improved condition of medical science and practice in the present day.

It is needless to recapitulate the difficulties encountered by the Medical Council in grappling with the problem thus proposed for its solution, many of the difficulties being intrinsic in the Council itself, most of the members of which are the paid officers, and the thick-and-thin advocates of the very institutions which stand in need of reform. The best course to pursue in the first place is undoubtedly that lately proposed, but not yet sufficiently carried out—namely, to appoint delegates to visit the different Examining Boards while the examinations are in progress, and to report honestly and impartially upon the facts they witness; adding their opinions as to the extent to which each Board discharges the duties entrusted to it, or how far it falls short of the requirements of the Medical Council.

But the Medical Act, while it clearly enjoins this duty upon the Council, has provided no machinery for

carrying it into operation, and, consequently, the Council is obliged to do the work itself as well as it can; and we not only fully understand the objections which have been raised against the efficiency of the present plan, but we can appreciate the feelings of reluctance which have been manifested by some members of the Council to undertake the invidious and often unwelcome duty thus imposed. It is a notorious fact, that the members of the Council are far from being agreed upon any common principle of action, and they differ from one another on almost every conceivable point of detail, although perhaps they may profess to entertain the same general views; and, moreover, it is not too harsh a remark to make, that not only are many of them opposed to one another in consequence of conflicting interests, but a few are actuated by something like personal animosity. But not only do national prejudices and jealousies run high in this select assembly of the Medical Profession, but even the representatives of the same nation are often more violently opposed to each other in their sentiments than they are towards those of a different country. Hence it is almost absurd to expect that a Visitation of Examinations conducted by the Council itself can be efficient, for either there will be a tacit understanding on all sides to conceal the real opinions of the visitors, or the reports will exhibit the personal prejudices or partialities of the reporters. It may fairly be doubted, too, whether all the members of the Council are competent to give authoritative opinions upon the points submitted to their judgment, for, without meaning any offence, we may remark that some of the nominees of the different corporations by no means occupy the same exalted position in professional esteem as that which is accorded to them by their own constituents, and even some of the more distinguished among the number are crotchety and impracticable both in their views and in the methods they propose for advancing them.

In some cases, again, the proposed Visitation of Examinations is either altogether superfluous, or it must necessarily degenerate into a mere farcical formality. We can conceive no possible good to result from sending (as it is proposed to do) Dr. PAGET, of Cambridge, to visit the Medical Examinations at Oxford, and Dr. ACLAND, of Oxford, to visit those at Cambridge; not because we disbelieve in the perfect integrity of either of those gentlemen, but simply because the examinations at both these seats of learning are very efficient, and, what is more, because they closely resemble one another. Let Dr. ACLAND and Dr. PAGET be sent to the Edinburgh or Glasgow University, and let Mr. SYME and Dr. ALLEN THOMSON be sent to Oxford or Cambridge University. In the diversities of education and examination existing in the respective institutions there would arise much material for useful reflection, and, as far as medical education is concerned, perhaps one institution might derive some valuable knowledge from another.

THE SCHOOL OF PHYSIC IN IRELAND.—III.

IN our last number we discussed the professorial arrangements of the School of Physic, and we now proceed to make some remarks on the clinical part of this School.

Sir Patrick Dun's Hospital was intended to be a copy, on a small scale, of the Royal Infirmary of Edinburgh; and hence we find that several of its clinical arrangements are based on that model. The Act of Parliament under which it was founded intended that it should provide accommodation for 100 patients, for whose medical attendance it made no provision. From these patients were to be selected certain cases for clinical observation in the shape of lectures; and these lectures were to be given by the Professors of the School of Physic. The treatment of surgical cases was not contemplated by the Act. Almost immediately after it had been opened, the Board of Governors—of whom more hereafter—had to appoint salaried Physicians in Ordinary to attend the greater part of the patients, leaving the Clinical Wards, which were closed, save during the Medical Session, to the care of the Clinical Professors. These wards, containing the cases selected for clinical purposes, were small, and were designed only for thirty patients.

The Clinical Instruction was at first, and for a long time, only given during the winter six months; but subsequently it was extended to the Summer Session, as at present. In 1865 it was resolved, with the consent of the College of Physicians, to admit surgical cases, and to give instruction in Clinical Surgery. This idea was not new. The teaching of surgery was part of the programme of education directed by Sir PATRICK DUN himself (see his "Memoir," by Dr. Belcher, page 50), in accordance with the then prevailing notion, that it was part of the Science of Medicine—an opinion which is again becoming fashionable; and so early as the year 1824, the late Dr. GRAVES proposed it in connection with this Hospital, but his proposal did not at that time meet with approval. Since then, however, the times are changed; and Sir PATRICK DUN's is now a Medico-Chirurgical Hospital, with a good Medical and Surgical Staff, and with a local situation which, however inconvenient it may have been as a place of meeting for the College of Physicians (who, as they were left DUN's house to meet in, had substituted the hospital for it as its legal representative), yet proved to be just the place for a Medico-Chirurgical Institution. It now became necessary to divide the Clinical Teaching into Medical and Surgical, and this was done by the consent of the Professors themselves. The Surgical portion was undertaken by the Professor of Anatomy, by the Professor of Surgery, who had long been Surgeon to the Hospital, and by the University Anatomist, who was elected Surgeon ex-officio. Instead of the ordinary system of having Resident Pupils, two Resident Medical Scholars were chosen, and the Board of Governors decided that the two Senior Medical Scholars of Trinity College

should in future fill these offices, ex-officio. The present Clinical system, not being that exactly contemplated by the Statute, is accompanied by inherent defects, by reason of which, except by an amended Act, it cannot work well in future. Except the Professors be specially chosen for Clinical merit—a thing not to be expected in all cases—it must fail, except it be supported by the good will of the Professors themselves. The Board of Dun's Hospital have no power over the original Professors, while they have power over the Professor of Surgery and the University Anatomist. The latter officer, it is obvious, may not in future cases be a fit person to be an Hospital Surgeon; he may be a Physician pure and simple, or merely an Anatomist. The same remark applies to the Professor of Anatomy; and on the medical side it applies in a corresponding or analogous degree to the Professors of Chemistry and Botany. Further, unless the Medical Scholars of Trinity College be chosen with a view to clinical usefulness, there can be no security that they will be fitted for the place of Resident Pupil. On the other hand, these ex-officio appointments, which originated with the Board of Governors, can be altered by the same Board; but the Act of Parliament, except by a general consent in partial obsolescence, will prove a dead-lock on the progress of the new system. By this Act, if carried out, Medical Students in general can never resort to Dun's Hospital in large numbers, for each Student who is of two years' standing in Arts in Dublin, Oxford, or Cambridge, must pay twelve guineas for a year's clinical privileges; while all Students in Arts who are under that standing, or the many who are not Students in Arts at all, must pay twenty-nine guineas for the like advantages. The Governors may receive and then return most of these fees, but in such case the College of Physicians, as trustees for the Professorship of Midwifery, are bound to interfere; for the fees thus received must be accounted for in the support of 100 patients, in close connection with which are the reversionary interests of the Professorship of Midwifery, as noticed in our second article.

If then no student in Arts of less than two years' standing can resort to this Hospital without paying twenty-nine guineas per annum, and if he can get recognised hospital instruction elsewhere for twenty guineas less, it follows that he will only go there for the minimum period required for the degree of M.B. Dub.—viz., one year; while other students will not go there at all; and if the Board of T.C.D. did away with compulsory attendance there for intending Graduates in Physic, as it might do since it is not required by the Act, no pupil would attend this Hospital. Hence the Act ought to be repealed as regards these fees. Under the present arrangement further imperfections exist. The Physicians in Ordinary are to be abolished, and the two existing Physicians in Ordinary are only continued to the end of the terms for which they were severally elected, because they were considered to have

vested rights. At present they only act during the autumn recess; but, once their term has expired, who will make the Clinical Professors attend in their stead? They are not required to do so by statute, and although they may attend daily during the Lecturing Session, they cannot be expected to continue their attendance during the time when they have no duties as Clinical Teachers. Nay, further: Any refractory Professor may refuse to attend daily at any time, seeing that he is only bound by statute to give, and paid for giving, two Clinical Lectures each week in his turn. There is no mention whatever in the Act of his being required to attend the sick at all; and though in ordinary cases he might be dismissed if he refused, yet here he cannot, at least for seven years after his election, for the Board of the Hospital neither elect nor control him. Further, if the Board of Trinity College do as they did once before, and elect a mere botanist as Professor of Botany in December next, having first legally qualified him by obtaining for him in the University of Dublin an honorary M.D., or by recognising such a degree obtained elsewhere—if in such case, the other Professors refuse to meet him on equal terms, as they ought, and decline to make any arrangement whereby he may be excused giving Clinical Lectures (as he is bound to do, and must *swear* he will do), then comes a hitch in the system which nothing but a fresh statute can remedy.

We hope to conclude this subject in our next.

THE MEDICAL CLUB.

FROM the success that attended the large and influential meeting of Thursday last, of which a report will be found in another column, we may now look upon the Medical Club as one of our professional institutions. The cordiality with which the speakers accepted the principle that a Professional Club is a desideratum, and would tend to promote the interests of our brethren, not only in London, but throughout England, Ireland, and Scotland, is a guarantee that the proposal will not now be allowed to drop. The simplicity and manliness with which Sir WILLIAM FERGUSSON advocated the claims of his medical brethren to social comforts, and illustrated the superiority of their Society to that of so many other classes, called forth the applause of the meeting and the thanks of succeeding speakers. His speech, in fact, afforded an example of that style of eloquence which consists in saying things appropriate to the occasion in the most natural and unpretending manner. We most cordially support Sir WILLIAM'S views, and offer our congratulations to the Club on having secured so able and influential a President. We are convinced, once established, its members will only wonder how they so long did without it. Politics of all shades, Literature, Art—all have institutions of this kind. Why not Medicine? A very short time ago the clergy established a club for themselves, and that, too, at about the same rate of subscription as that proposed for the Medical

Club. We mention this, because some of the speakers expressed a misgiving lest, on the terms named, it would be impossible to carry out the idea. On this point we must also add that there can be no doubt that, as in all other clubs, after a certain number have joined and the success is insured, the entrance fee and subscriptions will be increased. It is only just that those who found the institution should have the right to limit its numbers and fix the terms on which they will admit others to its benefits. Such a course tends to raise the status of the Club, and makes the privilege of admission considered more valuable. Let the Committee only conduct it in the best possible manner, and we should not be surprised to find the Medical Club as highly valued as the Athenæum. At present great advantages are offered to country members; it therefore particularly concerns such as may wish to join to do so without delay. Indeed, as it was announced on Thursday that more than 350 members had already been elected, we should suppose that at the first general meeting a proposal will be brought forward to raise the contributions of all future candidates. In no club that we are aware of, have more than 500 members been admitted at the original scale.

We believe that the Committee appointed at the meeting, by a judicious exercise of their "power to add to their number," may shortly put forth a list of managers that will be approved at the first general meeting. With Sir WILLIAM FERGUSSON for Chairman, and Mr. PROPERT for Treasurer, the profession in Great Britain and Ireland will not be wanting in confidence.

There are many points we should have been willing to touch, but would rather not take the initiative. Our columns are open to correspondence on the subject.

INAUGURATION OF THE STATUE OF SIR HENRY MARSH.

IN another column will be found an accurate report of this interesting ceremonial, furnished specially for publication in this journal. The speeches of Dr. STOKES and Dr. BANKS will be read with great interest; the latter giving a concise biographical sketch of the deceased physician, while the remarks of Dr. STOKES are especially brilliant on the subjects of the revival of Irish literature and medicine, of the fine arts in connection with our Profession, and of the spirit of modern criticism.

CHOLERA.

IN another column will be found an analysis of the public health during the quarter, founded on the official returns of the Registrar-General for that period. We have from week to week kept our readers *au courant* with the progress of the epidemic, and now that it is rapidly declining may still more briefly detail the chief items of news. In the forty-fourth week of the year, ending on the 3rd inst., 1316 deaths were registered in London. This is an excess of 116 over the estimated number. Only 73 deaths were registered from cholera as against 112 in the previous

week—a considerable decrease. There were, however, 28 deaths from diarrhœa, instead of 32. So that the total decrease in the week was 43, the deaths from the two forms of disease having fallen from 144 to 101. The most important point revealed in reference to these deaths is, that out of the 73 due to cholera, no less than 28 took place in Woolwich Dockyard and Plumstead. We last week directed attention to the outbreak in these localities, and urged upon the authorities the responsibility of their position. The whole history of the epidemic of 1866 has been one stern lesson on the perils of neglecting sanitary precautions.

The annual rate of mortality during the week was 24 per 1000 in London, 36 in Edinburgh, 38 in Dublin, 21 in Bristol, 20 in Birmingham, 37 in Liverpool, 38 in Manchester, 26 in Salford, 30 in Sheffield, 31 in Leeds, 20 in Hull, 38 in Newcastle-upon-Tyne, and 28 in Glasgow.

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29·843 in. The mean temperature of the air in the week was 49·2 deg., which is 2·7 deg. above the average of the same week in 50 years (as determined by Mr. Glaisher). The range in the week was 25·5 deg. The mean daily range was 12·0 deg. The difference between the mean dew-point temperature and air temperature was 3·4 deg. The mean degree of humidity of the air was 88, complete saturation being represented by 100. The direction of the wind was south-west. There was rain to the amount of 0·20 in. On Tuesday there was a gale of wind, and a pressure of 22·5 lb. on the square foot was recorded. According to a return furnished by the Metropolitan Board of Works the average daily quantity of sewage pumped into the river Thames at the southern outfall works, Crossness, was 44,526,623 gallons, or 202,305 metric tons.

We are happy to be able to add that the daily returns issued since the above week was completed show a continued decrease. Thus on Sunday and Monday together there were only 19 deaths from cholera, and 10 from diarrhœa. Of these one occurred in King's College Hospital, one in Guy's Hospital, and one in the Spitalfields Cholera Hospital. On Tuesday there were only 5 deaths from cholera, and 3 from diarrhœa. One of these took place in the London Hospital, another in Guy's. On Wednesday there were 14 deaths from cholera, and 1 from diarrhœa. On Thursday last there were 7 from cholera and 5 from diarrhœa.

CHARLTON.

The following is a summary of the statements made and the facts brought forward at a recent meeting of the Charlton Local Board:—The locality in which the disease first broke out on the 24th ult. was the Charlton marshes. On the evening of that day cholera suddenly appeared, and fourteen deaths occurred in almost as many hours. One of the members of the board described the conditions under which the insidious ailment had become manifest. The houses were built upon marsh land, which was so much a morass that the structures were positively sometimes moved when the river tide rose and fell. On the previous day a cottage on this ground was noticed apparently out of the perpendicular, and on applying the plummet discovery was made that the wall was swerved eighteen inches from upright. It was at that time high water. At low water the wall was tested again, and was found to have regained its upright position. Some of the

houses were fourteen feet below high water mark, and were surrounded by fœtid tidal ditches. In the vicinity of the place a farmer was accustomed to cover his land with blood, as a manure. A portion of a sewer had fallen there, and one of the streets (where a great proportion of deaths occurred) was broken up some years ago, when the main outfall sewer was constructed, and had not been properly mended since. Since the outbreak the Sanitary Committee met daily; medical visitors were appointed; three dispensaries were opened; the overseers were authorized to supply necessary nourishment and stimulants; the roads, &c., were watered with dilute carbolic acid; and other palliative measures were taken. The landlord had signified his wish in every way to assist the Sanitary Committee.

PILL, NEAR BRISTOL.

Six deaths have occurred in this village, and 25 cases are under treatment. This is scarcely to be wondered at, considering the sanitary condition of the place. There are only two pumps to supply a population of about 1500, and the unfortunate inhabitants are driven to the constant use of brook water, which is impregnated to a considerable extent with sewage. Very few of the houses are provided with privies, the drains are choked up, and the filth escaping from beneath the floors of the houses impregnates the whole atmosphere. Large quantities of excrementitious matter are daily thrown out on the banks of the river, and remain there for hours untouched by the tidal water. There is a public urinal, the whole of the filth from which flows into the cellar of an adjoining house.

THE NORTH.

The disease is declining in North Shields, but we regret to add that small-pox has appeared there. About 130 deaths from cholera and diarrhœa occurred during the month of October. The water suspected has been proved, on analysis, to be unfit for drinking, and a public meeting has been called on the subject. Further cases are reported from South Shields, Sunderland, and other towns. The Potteries district is also threatened—cases having occurred at Stoke-upon-Trent, and, unfortunately, the sanitary state of these towns affords means for the gravest apprehensions. In Derbyshire, also, several deaths have been reported, and some cases amongst the workmen of the Codnor-park Ironworks afford a pointed commentary on the article in last week's MEDICAL PRESS AND CIRCULAR, entitled "The Ironworkers' Strike and the Cholera."

EDINBURGH.

The weekly return shows the following cases of Asiatic cholera:—Attacks, 23; deaths, 14; recovered, 1; under treatment, 8. There were 17 attacks of British cholera and 16½ cases of diarrhœa during the week, but none of these proved fatal. The hospital has now been opened for four weeks, and, although the admissions have not increased, the average is kept up. The following are the numbers:—First week, 22; second week, 19; third week, 18; fourth week, 19. The cases in private practice during the week have been in the poorer districts, and in some cases the sufferers refuse to go to the hospital. The Sanitary Committee try to isolate the cases, and in no district has the disease yet become epidemic, though every quarter of the town has been visited. In Leith about 80 cases of Asiatic cholera have been reported, almost

entirely confined to one district. Of these 35 had ended fatally. The disease shows a decrease of 10 in the last weekly return. There is a falling off in the cases reported from Lochee, the average being now about one a-day. Isolated cases continue to occur at Dundee, Perth, and Aberdeen, also in Dalkeith, Prestonpans, and other towns and villages of the Lothians.

DUBLIN.

Cholera, which has been very prevalent and fatal for some time past in and around Dublin, appears, by the Irish Registrar-General's return for the week ending last Saturday, decidedly on the decrease, as may be seen by the following extract:—

"The deaths registered during the week were 230—115 males and 115 females. In the corresponding week of last year the number was 148. The deaths from cholera registered during the week amounted to 93, showing a decrease of 25 when compared with the number registered during the previous week. Of the 93 deaths from cholera, 13 occurred in the Kingstown district; 1 in Blackrock; 4 in Donnybrook; 1 in Rathmines; and 74 within the municipal boundary of Dublin. The number of deaths registered in Belfast during the week was 49; in Cork, 35; Limerick, 24; Waterford, 3; Galway, 10; Sligo, 6; Londonderry, 3; being at the rate of 21, 19, 25, 5, 21, 15, and 8 per 1000 per annum respectively."

Notes on Current Topics.

A MEDICAL PEERAGE.

THE propriety of recognizing the public services of eminent members of our profession, and at the same time adding strength to the deliberations of the legislative body on medico-sanitary measures, is appreciated more readily anywhere than in Great Britain. We learn from the *Evenement* that the anomaly of a Senate without a single representative of the strongest of the learned professions, or a single member capable of directing its deliberations on matters affecting the public health, has been lately, for the first time, brought under the notice of the Emperor of the French, who expressed his astonishment at the fact, and immediately issued instructions that his Majesty's Physician, Dr. Corneau, should be promoted to a seat in the French Senate. It is hard to comprehend why the French Government should have taken precedence of our own in such a matter. Is it because, we have had no physicians worthy of a peerage or capable of supporting its dignity? Is it because the administration of medical or sanitary affairs, under the direction of lawyers and merchants, is so perfect that no assistance is needed from the class whose special study they are?

THE QUEEN'S UNIVERSITY IN IRELAND.

A MEETING of the Senate of the University was held on last Thursday for further discussion of the Supplemental Charter. We understand that, by a majority of 9 to 6, it was resolved that the proposed alterations in the constitution of the University, in compliance with the new Charter, be proceeded with, and that the new regulations consequent thereon be issued as soon as possible. Proceedings have already been commenced in Chancery to restrain the Senate from carrying out this intention. The following legal opinion from the Attorney-General and Solicitor-General of the late Government has been obtained:—

"The following query was submitted for the joint opinion

of the Right Hon. James A. Lawson, Q.C., and Edward Sullivan, Esq., Q.C.:—

"Is the acceptance of the Supplemental Charter of 1866, by the Senate only of the Queen's University in Ireland, a valid act; or is it, in your opinion, liable to be declared null by any court of law or equity?"

"Will degrees, granted under the authority of the Supplemental Charter of 1866, have all the force intended by that Charter?"

[Copies of the Charter of 1864, and of the Supplemental Charter of 1866, are sent.]

"The following is the joint opinion of the late Attorney-General and Solicitor-General:—

"We are of opinion that the Senate of the Queen's University has power to accept the Supplemental Charter of 1866, and their acceptance of it constitutes a valid act, and we think that no court of law or equity can legally set it aside. We further think that degrees granted under the authority of the Supplemental Charter will have all the force contemplated by that Charter.

"Nov. 7, 1866."

"JAMES A. LAWSON.
"EDWARD SULLIVAN."

THE LATE APPOINTMENT TO THE IRISH POOR-LAW INSPECTORSHIP.

WE refer to the late appointment at present, only to say that the statement as to the appointment of Dr. Roughan is not, as said by the *Dublin Evening Mail*, premature. We have seen a letter from the Commissioners which concludes with these words—"The choice has fallen upon Dr. Roughan of Ballinrobe, who has been appointed accordingly."

SANITARY CONDITION OF INDIAN TOWNS.

THE Bombay Sanitary Commission has undertaken the inspection of some of the towns in that Presidency, with a view of ascertaining what improvements are absolutely necessary. Dr. Leith has reported that numerous measures ought to be undertaken to preserve the water from pollution, prevent to some extent the loading of the atmosphere with pestilential effluvia, and secure other conditions essential to health. It is impossible to detail the actual state of all the towns visited by Dr. Leith, who is President of the Commission, as well as Duputy-Inspector-General of Hospitals. We may, however, take one as an illustration, merely premising the well-worn quotation, *ex uno disce omnes*. The town of Sholapoor, in Poonah, has a population of upwards of 30,000. The houses are the most part built in enclosures fronting towards a street or alley. The dead walls are often of mud, in which a small doorway is the only opening. Inside the door is a yard about 10 or 12 feet square, on the sides of which are the dark rooms or cells in which the people live, with an open verandah before them. The rooms are generally very little ventilated, and lighted by an aperture about a foot square. The yard may communicate with one or more others, or there may be a labyrinthine succession of such courts. The houses within the walls are visited by sweepers at longer or shorter intervals. Drainage there is none, but there are vile and offensive receptacles in the enclosures, consisting in the poorer houses of nothing but a screen wall, behind which there is no vessel, merely the bare ground, which thus becomes saturated with filth. The foul waste water of houses, abutting on a street with a side-gutter, is discharged into that gutter, there to evaporate. When there is no gutter, an unglazed earthen jar is sunk at the side of the lane or street, and a pipe passing through the wall pours the liquid into it. When full, the jar is supposed to be carried away outside the town to be emptied. Some of the wealthier houses have masonry cesspits instead of the

porous jar, and in this, as well as generally in the former case, the contents are baled or thrown out on the neighbouring road, there to be absorbed or to evaporate. Many merely dig a hole at the side of the street for the reception of the liquid refuse; and this more pernicious, absorbing cesspit, gives them less trouble than the jar, as a longer time elapses before it requires to be cleared out. When the time does come for this, the fœtid mud accumulated in it is scattered over the neighbouring ground. Were it not for the dryness of the air, human life could scarcely be maintained under these conditions. In a moist climate such prevalent uncleanness would occasion devastating pestilence. Water is obtained chiefly from the Sideshwur tank, which has been excavated at the south of the town, and which is now protected by the police from washing or bathing; but the ancient custom is still followed of drawing water by standing in it, and scrubbing the water-vessels in it. When the rains cease, the impurities of this tank become concentrated, and in the hot season it dries up. A large quarry hole, Khundoba Tulao, is used for the collection of surface water. This water, which the people consider good, is greatly defiled; and persons were seen bathing and washing their clothes in it while others were drinking or drawing water from it beside them. The municipality has liberally provided a large number of wells, which high-caste people will not use, but which are of service to those who are by other Hindoos considered beyond the pale of social intercourse. The scarcity of good water leads many of the townspeople to seek it in the military cantonment, which adjoins the town. In the sleeping rooms of the gaol Dr. Leith found the allowance to be only seventeen-and-a-half square feet of floor and 201 cubic feet of space, with an inlet for fresh air of sixteen square inches, and an outlet for foul air of two-and-three-quarters square inches only. Yet the municipality of this town has a revenue of 30,000 rupees from the taxation. It is to be hoped some of Dr. Leith's recommendations will at once be adopted.

LEGAL INTELLIGENCE.

IMPORTANT TO THE MEDICAL PROFESSION.

COLEMAN v. THE KILRUSH BOARD OF GUARDIANS.

At the Quarter Sessions at Kilrush, this case was tried before Michael O'Shaughnessy, Esq., Q.C. (Chairman). Dr. William St. John Coleman, of Miltown Malbay, was complainant, and the Kilrush Board of Guardians, defendants.

Dr. Coleman examined by Mr. Henry Reilly—Deposed that on the 11th December last, he had been called in consultation with Dr. Rowan, Medical Officer of the Cragnoek district of the Kilrush Union, in a difficult midwifery case, in which an operation had subsequently to be performed. The patient's house was situated about three or three-and-a-half miles from his residence, and the time occupied in consultation, operation, &c., about three hours; had applied to the guardians for a fee of £2 2s., which was the recognized fee, in consultation; was awarded £1 1s., by the board, but refused to take less than the recognized fee.

By the Chairman.—Had to deliver the woman instrumentally; was offered £1 1s., by the Board, but refused it on the grounds that it was insufficient.

Cross-examined by Mr. Frost (Solicitor to the Board)—Was not present at the Committee, when fee of £1 1s., was adjudged; was not aware that it was unanimous, on the contrary heard that the Chairman, Mr. McMahon, J.P., expressed his opinion that it was no use in offering it as he knew it would not be accepted; did not know that £1 1s. was the fee allowed by the Board, and refused to allow the Board to dictate to his profession, or set a value upon his services personally.

Mr. A. Warren, Clerk of the Board of Guardians, pro-

duced receipts of medical men for £1 1s., paid them on such occasions, and deposed that such was the fee directed by the Board.

Dr. J. F. Rowan stated the services rendered him by Dr. Coleman, and his belief, that the fee demanded was in accordance with the recognized scale.

Dr. Coleman, in answer to the Chairman and Mr. Reilly, said that Dr. Shannon had been paid a similar demand in his (the Ennistymon) Union, for similar services.

Mr. Michael O'Loughlen, barrister, addressed his Worship on the assumption of such authority by the Board, arguing that in such an arbitrary conclusion every profession was concerned. The case under discussion that day might be applied to themselves next day. If members of the Medical Legal Profession—and he regretted there were such men—took less than the recognized fee of their body, they did not bind others thereby, nor arrogate the Boards of Guardians the power to regulate a scale of charges to the different professions. Dr. Coleman deserved much sympathy and credit for his pluck in defending the rights of his profession, and in refusing to be dictated to in respect to the value of his professional services.

His Worship, who said he felt no hesitation whatsoever in the matter, at once gave a decree for the amount claimed, £2 2s.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

OCTOBER, 1866.

THE Quarterly Examinations in General Education were held on the 31st ult. and 1st inst. The answering in general was satisfactory; and in every instance of postponement of the granting of a candidates' certificate, failure was altogether or mainly due to deficiency in Greek and Latin. We subjoin the Examiner's paper in arithmetic for the information and guidance of our young friends:—

ARITHMETIC—DR. MURRAY.

The Candidate will write the result at which he arrives after the word Answer, and furnish the work on the blank paper supplied to him, taking the questions in any order he pleases.

1. The Ex-Chancellor of the Exchequer stated not long ago that he believed there were not thirty Members of the House of Commons who could divide £1330 17s. 6d. by £2 13s. 8d.; will you attempt the feat? Answer.

2. At a recent Irish Election the number polled was stated to be 6284, and the successful one of two candidates was said to have a majority of 554; how many voters did each candidate poll? Answer.

N.B.—Show on your blank paper that in such a constituency, the majority of either candidate could not possibly be an odd number, however it might vary.

3. What is the joint product of the digits from 1 to 0 inclusive? Answer.

4. How many ounces in a cubic foot of water? Answer.

5. In what time will the interest of £997 13s. 4d. amount to £20 18s. 6½d. at 6½ per cent.? Answer.

6. Compute by the rule of Practice the amount of 6 oz. 18 dwts. 20 grs. at 7s. 9d. per oz. Answer.

7. Extract to five places the square root, and to four places the cube root, of 2.5. Answer.

8. Find the greatest common measure of 10,000 and 3775. Answer.

9. Find the least common multiple of the digits from 1 to 9 inclusive. Answer.

10. The square root of $\left\{ \frac{\frac{4}{9}}{\frac{9}{16}} \right\}$ is evident on inspection: in decimal expression, what interminable digit will represent it? Answer.

11. Write the preceding compound fraction, first, as expressing parts of a pound sterling, and next as representative of a portion of a shilling. Answer.

12. If the division implied in Question 1 be carried out in each instance included in eleventh Question, the pecuniary value of the sum of the square roots will be an even amount of shillings and pence; what is it? Answer.

INAUGURATION OF THE STATUE OF THE LATE SIR HENRY MARSH, M.D., BART.

THE interesting ceremony of the inauguration of the statue of the late Sir Henry Marsh, M.D., took place on the 9th inst., at the King and Queen's College of Physicians, Kildare-street, Dublin. It will be within the recollection of our readers that shortly after the death of this distinguished physician a movement was set on foot by a number of his colleagues and former pupils to perpetuate his fame by a suitable memorial, and a committee was formed for the purpose. It is a very gratifying indication of the spirit in which the memory of Sir Henry Marsh is cherished to find that the labours of this committee were by no means arduous, and that in a very short time a sufficient amount was subscribed to defray the cost of the very handsome statue which was decided upon as the best form for the memorial. The ceremony was to inaugurate the statue by presenting it on the part of the subscribers to the King and Queen's College of Physicians, of which he was so eminent a member, and was, on six different occasions, elected to the honourable position of its presidency. The statue, which stands on a pedestal on the left side of the convocation-room, was executed by Mr. Foley, R.A., of London, and the truthfulness of conception and perfection of execution by which it is distinguished furnish another and pleasing proof of the artist's signal ability in a profession of which he has become one of the greatest ornaments. The figure, which is of life-size, draped in the full academic costume of the President, is in the attitude of reasoning—the right hand being raised as if in the act of argumentation, and the left foot advanced about half a step; the left hand reclines gracefully by the side, and holds a college cap in a remarkably unaffected and pleasing position. The head is thrown slightly forward, with an inclination to the right side. The face is singularly well cut; the highly intellectual expression, the quiet determination, as of a thinker deeply in earnest, are delineated with the most exquisite delicacy and finish.

Dr. STOKES, President of the College, occupied the chair, and there were also present the following Fellows:—Dr. Adams, Dr. Atthill, Registrar; Dr. Beatty, ex-President; Dr. Belcher, Censor; Dr. Churchill, Sir Dominic Corrigan, ex-President; Dr. Croker, ex-President; Dr. Cruise, Dr. Duncan, Dr. Dwyer, Treasurer; Dr. Freke, Dr. Gordon, Censor; Dr. Guinness, Dr. Jennings, Censor; Dr. Johnston, Dr. Henry Kennedy, Dr. Lyons, Dr. Mollan, ex-President; Dr. Moore, Vice-President and Censor; Dr. Ringland, Dr. Sinclair, Professor of Midwifery; Professor A. Smith, Honorary Fellow; Professor Banks, Honorary Fellow.

The President (Dr. Stokes) wore the handsome costume of his office, and the Fellows present wore the hoods of their several degrees over their ordinary academic costume.

Among the visitors present were—Sir William Wilde, Dr. Hardy, Dr. McClintock, Dr. McSwiney, Dr. Carroll, Dr. Kidd, Dr. Forrest, Dr. Eustace, Dr. W. D. Moore, Dr. Thornhill, Dr. Madden, Dr. Nalty, Dr. Banks, Dr. Nelson, Dr. Cunningham, Dr. Byrne, Dr. O'Reilly, Dr. Mahon, R.N.; Dr. Owens, Dr. Hayden, Dr. Monks, Dr. H. Sibthorpe, Dr. Nedley, Dr. Hildige, R. Colvill, Esq.; H. C. Whyte, Esq.; —Denny, Esq.; Lord James Butler, C. Stanford, Esq.; H. Lindsay, Esq.; —Wybrants, Esq.; J. Jameson, Esq.; —Lembreck, Esq.; Sir Richard Griffith, C. Otway, Esq.; C. Fleming, Esq.; J. Robinson, Esq.; John E. Naghten, Esq., A.B.; R. Callwell, Esq.; J. R. Garstin, Esq., &c.

The following gentlemen represented the subscribers, for the purpose of presenting the statue:—Lord James Butler, Sir Richard Griffith, General O'Neil, Mr. Lendrick, Mr. Wybrants, Mr. Thornhill, Sir W. Wilde, and Mr. Stanford.

Dr. Banks, King's Professor of Physic, opened the proceedings with the following address:—

Mr. President,—On the part of a large number of the general public, as well as of very many members of our pro-

fession, I am here to-day to present to the King and Queen's College of Physicians in Ireland a gift of no ordinary value—the statue of an eminent physician and a distinguished member of this College, the late Sir Henry Marsh. Attached to him as I was by the closest ties of friendship and affection from my boyhood to the last hour of his earthly existence, it is deeply gratifying to me to find myself an agent in the final act of our proceedings for the perpetuation of his memory. Although his name and his fame, as one of the leading physicians of this city, were before the public for more than a quarter of a century, it may not be out of place on an occasion like this briefly to review the most prominent incidents of his career. The junior members of our profession may derive no small profit by contemplating the life of him who had so borne himself during the allotted period of human life as to be deemed worthy not only of the favour of his Sovereign, but of the highest honour and respect in the power of his countrymen to confer. The lives of physicians are rarely marked by events of startling interest, and so it must be from the nature of their avocations, their habits of life, and modes of thought, even when the highest success and its attendant honours are attained. Sir Henry Marsh was born in the county Galway towards the close of the year 1790. His father was Rector of Loughrea. Of his remote ancestry it is sufficient to say that among them will be found names well known amongst the nobility of rank and intellect. After a successful undergraduate course in Trinity College, he graduated in arts in 1812, and in medicine in 1818; and in the same year he became a licentiate of the King and Queen's College of Physicians. In 1820 he was appointed one of the physicians of Stevens' Hospital, and to this circumstance may be fairly traced the foundation of his great fame as a practical physician. In conjunction with Graves, Cusack, Wilmot, and Jacob, he founded the once celebrated School of Medicine in Park-street, an institution remarkable for having supplied with professors the School of Physic and the Royal College of Surgeons in Ireland. About the same time, aided by the late Dr. Charles Johnson and Dr. Cuming of Armagh, he established an Institution for the Diseases of Children, now situated in Pitt-street. In 1827, on the resignation of the late learned Dr. Whitley Stokes, he was nominated Professor of the Practice of Medicine in the College of Surgeons, an appointment which, however, he resigned in 1832, feeling that the exigencies of large and increasing practice rendered it impossible for him to discharge its duties conscientiously and efficiently. Endowed with remarkable powers of observation, he was prepared to turn to the best advantage the opportunities he enjoyed as physician to Stevens' Hospital, and thus he acquired that large experience and that profound knowledge of disease which caused his opinion to be so frequently sought and so highly prized in cases of doubt and difficulty. The first fruits of his clinical researches may be seen in the "Dublin Hospital Reports," where we find contributions from his pen of great and abiding value. Of the essays published at this period I would especially direct attention to those on the origin of fever, on jaundice, and on spasms of the glottis. In later years, and in the plenitude of his great experience, the all-absorbing duties of extensive practice prevented Sir Henry Marsh from contributing as much as could have been desired, and as he himself wished, to medical science; nevertheless, from time to time he published in the *Dublin Quarterly Journal* and in *THE DUBLIN MEDICAL PRESS* papers of great importance, and lectures replete with sound practical information. Of those who with Marsh co-operated in laying the foundation of the Irish School of Medicine in the "Dublin Hospital Reports," how few remain to enjoy the exalted position to which their labours so well entitle them! Sir Henry Marsh's rise in the estimation of the public and in the confidence of his own profession was rapid, and the eminence once attained was unshaken to the last moment of his life. This circumstance was in a great measure to be attributed to the fact that in all his relations with his brethren his conduct was ever guided by the nicest feeling of delicacy and the strictest sense of honour. The highest distinction in the power of this College to confer having been freely and repeatedly bestowed upon him, he received the honour of Baronetcy in 1859, at the same time with his friend Sir P. Crampton, whose pupil he had formerly been. It may be interesting, in connection with this event, to mention that Sir T. Molyneux, the first physician in Ireland ever raised to the dignity of a Baronet, was a maternal

ancestor of Marsh. Six years have nearly elapsed since, in the apparent enjoyment of perfect bodily health, and in the full vigour of his mental powers, Sir Henry Marsh was suddenly removed from amongst us by the hand of death. Many who are present will remember the painful feeling of regret which pervaded all classes of society in this city when it became generally known that he, who had so often warded off the assaults of disease in others, had himself been stricken down. On those who had the happiness of enjoying the closest intimacy with the deceased, and were within the circle of his chosen friends, the blow fell heavily; they experienced a shock the severity of which no words of mine can adequately express. The genial and hospitable gentleman, the true-hearted friend, and the great physician, was no more. Painful was the feeling that we should for ever miss "the touch of the vanished hand and the sound of the voice that is still." In a few days after the grave had closed over him whose memory we are here to-day to honour, it was arranged that a meeting of his friends should be called, for the purpose of devising some means of manifesting by a permanent memorial the respect in which his memory was held. The meeting was fitly presided over by the late Mr. Cusack, who was his old colleague and life-long friend. The first resolution adopted at this meeting was—"That the high position which Sir Henry Marsh so long held in the estimation of his professional brethren and of the public should be marked by some lasting testimonial of his eminent abilities." It was subsequently agreed upon by the committee that a marble statue, to be placed in the hall of the College of Physicians, would be the most suitable form for the testimonial. This proposal was submitted to a general meeting, and unanimously adopted; the subscribers who had no connection with our profession agreeing with us that the College over which he had so often and so efficiently presided, and with which he was so long and so intimately connected, would be the most appropriate site which could be selected for the statue. It now remains for me to call attention to the admirable manner in which the work entrusted to Mr. Foley has been executed. I speak the opinion of those more competent to judge than I am, when I affirm that the statue of Sir Henry Marsh is one of the most successful efforts of our highly-gifted countryman. In presenting the statue to the College of Physicians, in the name of the subscribers, as I now do, I have no doubt of the value which will be attached to it by those upon whose memories the features of our departed friend are indelibly impressed. The statue will be appreciated for its marvellous likeness; and by those who are to succeed us in this College, and who never looked upon the original, it must be prized for its own intrinsic worth, as a rare specimen of a great sculptor's skill. And now, sir, having performed my allotted work, I must crave your permission to make one additional remark. To myself, and to those who have been associated with me in bringing to a conclusion the duties which we undertook, it is a subject of much gratification that the chair of this College should be at this time occupied by one who, like Sir Henry Marsh, has ever laboured to maintain the honour and dignity of the profession, and to elevate the social and scientific position of medicine in this country.

The President, Dr. Stokes, then replied as follows:—Dr. Banks, and Gentlemen of the Deputation,—It is now my grateful task to offer, on the part of the King and Queen's College of Physicians in Ireland, our thanks for the noble gift you have made to us. In choosing as the proper site for this memorial statue the hall of that College of which he who is gone was so long an honoured member, you have typified his devotion to medicine and to this institution, of which he was once the head, and always the ornament. Ireland does not want for representative men. She can proudly point out many such in arts, in arms, in science, and in literature, in poetry and in oratory; and among the leading men in Irish medicine, Marsh can fitly claim a place. You may rest assured that his statue will be affectionately and carefully preserved by us, and, we trust, by those who will succeed us, not alone on account of its surpassing merit as a work of art, but in memory of an earnest and successful worker in science. The great physician, the true friend, and the thorough Irish gentleman, Sir Henry Marsh, was one of that noble band of men whose labours marked the intellectual uprising of this country after the lapse of nearly a quarter of a century, which followed 1800. It was the time of Brinkley, of Lloyd, of Hamilton, of MacCullagh, and of Butler, of Apjohn, of

Robinson, of Kane, of Petrie, of Todd, of O'Donovan, and O'Curry, of Anster, of Carleton, of Griffin, of Mangan, of Ferguson, and of McCarthy; and in Medicine, of Cheyne, Coles, Carmichael, and Cusack, of Graves, Corrigan, Adams, Jacob, Smith, Beatty, Montgomery, and many more. It was at this period the University received its great impulse, in consequence of the reforms introduced by Provost Lloyd, when the Royal Irish Academy showed signs of a new and vigorous life, in the creation of its museum, by our great countryman, Petrie,—when the Zoological and other scientific bodies were founded—when new schools of medicine and surgery sprang up—when the *Dublin Journal of Medicine* was established, when the *University Magazine* first appeared, and when the great project of the topographical survey of Ireland was organized by Sir Thomas Larcom. It was, in brief, a time when the mind of the country seemed to wake up to a consciousness of its power, and saw the work that was before it. It must be gratifying to this College to see this noble hall, in which we are now assembled, becoming, as it were, the Irish Medical Walhalla, where will be preserved the memorials which, though dead, yet speak of those true soldiers of medicine whose works live after them, and whose ways were worthy. We have the bust of Graves, by Hogan, of that great and philosophic teacher, who founded and built up the fame of the Irish School of Clinical Medicine. We have the bust, in clay, of Sir Dominic Corrigan, Bart., to whose exertions we are indebted for the building in which we are assembled. It is from the hand of the master who fashioned this figure, and we are promised soon a more ambitious and finished work. We have the portraits of Dun, of Percival, of Cheyne, of Brooke, of Mills, of Barry, of Corrigan, and of Mayne; and so we are following in the steps of the Royal College of Physicians in England, on whose walls hang so many noble portraits of the noble fathers of British medicine. Like many other places, Dublin is deficient in monuments of this kind; and even where members of our profession have conferred lasting benefits by founding great institutions for the purposes of charity and science, we miss their monuments. In our great Lying-in Hospital there is a plaster cast of the founder, with the inscription "Miseris solamen instituit." Why should not his statue adorn this hall? So again, at Steevens' Hospital, a simple tablet records the name of the founder and the pious work of his sister; and, to come to ourselves, we have not even a portrait of Stearne, our founder, in the reign of Charles II., and whose history has been so ably worked out by one of our Fellows, the learned Dr. Belcher. But, indeed, few members of our profession have been honoured by statues. The statue of Dr. Lucas, in the Corporation Hall, was erected from political considerations in the last century. Those of John Hunter and the late Dr. Robert Bentley Todd are, like that of Marsh, fitly placed in the scene of their labours, and the only public statue to a physician in these countries is that of Jenner. This was lately removed from Trafalgar-square to a more obscure position. How slowly do our barbaric traditions depart from us! But in time mankind will learn that to save is more excellent than to destroy; and that the great physician, as well as the great soldier, if he has done his duty, is equally entitled to honour. The art of the sculptor has various objects, and, consequently, in its execution the artist is guided by different principles. His work may be intended as a part of a great architectural whole, as in the case of the figures over the portico of the Bank, and the admirable symbolic heads of the river deities of Ireland, which adorn the arches and windows of the Custom House; or it may be for a public statue, in which the figure, if not colossal, is more or less idealized, the accuracy of the likeness, though important, being made subsidiary to the general effect; or the statue may be intended as a portrait of one whom his children and children's children, his friends, his fellows, and their successors, wish to keep in the lasting marble ever before them.

"As when a painter, poring on a face,
Divinely through all hindrance finds the man
Behind it, and so paints him, that his face,
The shape and colour of a mind and life,
Lives for his children, even at its best
And fullest."

This statue, as well as that of Goldsmith, both from the chisel of Mr. Foley, are admirable examples of the latter class. To the observations of Dr. Banks on the merits of the work it would be superfluous to add anything. There are few, if any, works of art, even those of the best Greek

period, to which that kind of criticism which consists in fault-finding may not have room to apply. But, as a great writer has remarked, we should not seek to detect deficiencies and imperfections in works of art until we have learned to recognize and discover their beauties. This power of seeing and feeling the beautiful and true is so rarely met with that the term "criticism" is commonly held to mean depreciation. Those who follow this method are always vain, often ignorant, or imbued, as Winkleman has it, with excess of caution. They appear to have determined to admire nothing, because they believe admiration to be an expression of ignorance, forgetting what Plato says, that admiration is the sentiment of a thinking mind, and one of the avenues which lead to philosophy. I have but to add, that the situation of the statue was chosen by Mr. Foley, and that the pedestal, also designed by him, has been gratefully furnished by the College.

Lord James Butler said he had been requested to propose a vote of thanks to the subscribers and committee, through whose exertions they had been enabled to raise the memorial, presented that day to the King and Queen's College of Physicians, to the late Sir Henry Marsh. His character had been so fully dwelt upon by Dr. Banks, that it was quite unnecessary that he should then refer to it. His fame was known everywhere, and it was such as not to be readily exceeded. Of his fame as a physician it did not so much become him to speak, but he might say, having had the honour of knowing him for many years, it was only exceeded by his hospitality and generosity. He spoke from circumstances within his own knowledge of his extreme kindness of heart, in which he could not have been excelled by any. They were indebted to the committee for having brought their labours to so successful an issue. They were indebted to them also for the selection of the artist, who, in sending that statue to decorate their hall, had sent from his chisel another admirable specimen of art, which made it their pride that he (the artist) should belong to them. In conclusion, he had only to add that in the statue they would all recognise the features of him they had so well known, and which proved how well the committee had carried out the wishes of the subscribers.

General O'Neil said—I feel it a high honour to be called on to second this motion, and I have the utmost pleasure in doing so.

The resolution was carried with enthusiasm.

Sir Dominic Corrigan then rose and said the committee had kindly requested him, as their Chairman, to return thanks for the flattering compliment which had been passed in the form of a resolution for the labour it was alleged they had undertaken in the matter. Before he proceeded further in returning thanks, he might be permitted to say—and he was sure he only echoed the voice that would come from every one present, and only gave expression to the thought that rose to every one's mind—that in the galaxy of names which had been enumerated as reflecting so much light upon science in Ireland, and particularly upon the science of medicine, one name had been omitted—the name of Stokes (applause). The labour which the committee had had to go through was a labour of love, that arose out of a deep feeling of regard for the loss they, in common with the public, had sustained. For any effort they had made they desired no thanks; they were already more than repaid for all they had done. Their proposal was so well received that they had nothing more to do than the merest routine that could fall to the hands of any committee to whom such labour was entrusted. Sir Henry Marsh, their Chairman had well remarked, contributed much to the progress of medicine. That was one way in which they were indebted to him. Another was in his transmitting to those who came after him those properties—the tact, the indescribable relations that bound them to each other—which they could not envelope in books, which they could not even convey in writing, but which were their guides. In the second quality he excelled, and to him they were indebted for the information he gave them, and for the manner in which he transmitted the knowledge he had acquired from those before him. There was a third point, the value of which not only they themselves, but those outside the profession, must know the blessing of: he was one of those who inherited the mantle that came from above, and had transmitted it, he (Sir Dominic) hoped, to some one present in the room—namely, the mantle of kindness and good fellowship, of humanity and charity, of good-will and affection—

qualities which were exhibited in the profession in Dublin to a degree not excelled throughout Europe. For in the profession in no part of Europe, he believed, could those qualities, which tended so much to elevate the profession, be seen in greater perfection than in the city of Dublin. The public were more interested in them than they at first sight might think, for if there were not that community of feeling, that kindness of disposition, that mutual affection existing among their members, there could not be the free interchange of professional knowledge, which tended, not alone to elevate the profession, but very much, indeed, to the benefit of the public and the poor who were entrusted to their care. In those qualities his great example came down to them, and none could do better than remember those moral qualities which he so well observed, and, imitating him, hand them down to those who, in the natural order of things, would succeed them (hear, hear). Sir Dominic concluded by moving that the President do leave the chair.

The Vice-President having been moved to the second chair,

Dr. McClintock moved a vote of thanks to the President for his conduct in the chair.

Sir Richard Griffith seconded the resolution, which passed unanimously.

The proceedings then terminated.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their Primary Examinations in Anatomy and Physiology, at a meeting of the Court of Examiners, on November 6th, and when eligible will be admitted to the Pass Examination:—

Henry Prescott Roberts, Samuel Burton, and Alexander Richardson Haughey, of the Edinburgh School; John Baddock Harris and Thomas Vincent de Denne, of St. Thomas's Hospital; Joseph William Plaxton and William Vaudy, of Hull; Tullius William Ward Fay, of Liverpool; Robert George Fendick, of Bristol; Charles Henry Stanley Stevens, of St. George's Hospital; James Peter Byrne, of Dublin; George May, of King's College; Alexander Dyce Davidson, of Aberdeen; Samuel Jackson, of Guy's; Frederick Augustus Alfred Smith, of the London Hospital; John Hickman Hiron, of Birmingham; and Joseph Foster, of University College.

It is stated that only five candidates out of twenty-two failed to acquit themselves to the satisfaction of the Court, and were consequently referred to their studies for three months. The "Pass" or Surgical and Pathological Examination took place on Saturday, Nov. 9th.

APOTHECARIES' HALL OF LONDON.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Nov. 1st:—

Bonney, Wm. Augustus, Elm House, Brompton.
Crew, Eli, Tetbury, Gloucestershire.
Dyer, Thomas Bireh, Guy's Hospital.
Ireland, Edward, Kendal, Westmoreland.
Stokell, George, Guy's Hospital.

The following gentlemen also on the same day passed their first examination:—

Octavius Twigg Molecey, King's College Hospital; Charles Munden, Guy's Hospital; Salthern G. Litteljohn, St. Thomas's Hospital; Augustus Constable Maybury, St. Thomas's Hospital; Richard Wilson, St. George's Hospital.

At the competitive examination, on Oct. 17th and 19th, for the prizes in Materia Medica and Pharmaceutical Chemistry annually given by the Society of Apothecaries, the successful candidates were:—

1. Albert Henry Baines, Guy's Hospital; Gold Medal.
2. Jas. Goodridge Anderson, St. Mary's Hospital; Silver Medal and a Book.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—The following gentlemen passed their final examinations, and were admitted Licentiates of the College, during the October sittings of the examiners:—

Black, Donald Campbell, Argyllshire.
Carmichael, Thomas, County Antrim.
Hay, George William Robertson, Roxburghshire.
Hume, George Haliburton, Berwickshire.
Laing, James Anderson, Edinburgh.
Macalevy, Robert Peel, Scarva.
M'Caw, John Dysart, Portglenone.
Mullan, Andrew, Banbridge.
Ross, John Ralph, Drumbrain.
Stirling, Stewart, Kilsyth.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH: DOUBLE QUALIFICATION.—The following gentlemen passed their final examinations, and were admitted L.R.C.P.Edin. and L.R.C.S.Edin., during the recent sittings of the examiners.

Bath, Henry, Glastonbury, England.
Boyd, John Stewart, County Tyrone.
Brownrigg, Henry Thomas, Waterford.
Cane, James Butler Norris, Kilkenny.
Dods, George, Haddington.
Garde, William Henry, Australia.
Masson, William Herbert, India.
Nason, Henry Wilson, Dublin.
Riddell, John, County Monaghan.
Sinclair, George Murray, Tranent.
Stockwell, James, Musselburgh.

During the same sittings the following gentlemen passed their first professional examinations:—

Roderick Macdonald, Skye; Philip S. Warren, Cork; Richard Sullivan, Bandon; Daniel Heagerty, Cork; Benjamin Bain, Calthinesshire; John Murray, Drug; James Walsh, Castlebar; James S. Conway, Limerick.

LIST of Entries in the Register of the Branch Medical Council, Ireland, for the month of October, 1866:—

Archdall, Gordon, Archdall Lodge, Bundoran, county Donegal, L.K.Q.C.P.I., 1866; M.R.C.S.Eng., 1866.
Pendleton, Richard Warren, Stillorgan, county Dublin, L.R.C.S.I., 1865; L., 1866, and L.M., 1866; K.Q.C.P.I.
Hart, Patrick Joseph, Clifden, county Galway, L.R.C.S.I., 1866.
Haliday, Saunders Barton, 13, Great Brunswick-street, Dublin, M.R.C.S.Eng., 1863; L.R.C.P.Edin., 1866.
Watkins, William Longworth, Drumlish, county Longford, L., 1866, and L.M., 1866; K.Q.C.P.I., L.R.C.S.I., 1866.
De Merie, Eugene Victor, 37, Lower Gardiner-street, Dublin, L.R.C.S.I., 1866.
Wodsworth, Charles Gregory, Sandycove, Kingstown, county Dublin, L.R.C.S.I., 1866.
Webb, Robert Andrews, Ross House, Tara, Navan, county Meath, L.F.P. & S.Glasg., 1866; L.R.C.P.Edin., 1866.
Young, Alexander, Ballymena, county Antrim, L.R.C.S.Edin., 1865; M.D.Q.U.Dub., 1866.
Wade, Robert, 208, Great Brunswick-street, Dublin, L.R.C.S.I., 1864; L.A.H.Dub., 1865.
Carey, Richard Browne, Newtownbarry, county Wexford, L., 1866, and L.M., 1866; K.Q.C.P.I., L.R.C.S.I., 1866.
Olden, Dominick Lynch, Dungarvan, county Waterford, L., 1866, and L.M., 1866; K.Q.C.P.I., L.R.C.S.I., 1866.
Rawson, Edward Albert, Barrowville, Carlow, L.R.C.S.I., 1865; L.M. and L.S.U.Dub., 1865.

Notices to Correspondents.

Mr. James Weston.—It would be impossible for us to insert your letter. Your case is, unfortunately, but the type of thousands, and in the present unsatisfactory state of the law in regard to medicine and medical practitioners, prosecution would be useless. Your only remedy is to apply to the magistrate in whose jurisdiction you meet with such abominable treatment, and he would doubtless give you the advice necessary for the furtherance of so desirable an object.

Dr. Althaus's communication shall have attention.
M.D., T.C.D.—Your paper on "Eczema" has been received, and shall appear in our next.

B. B.—Your communication is not so satisfactory as we could wish; nor would it serve the interests of the profession.

Mr. E. Wylie.—The notice is inserted.

Mr. H.—The subject is under consideration.
A Subscriber, who writes on the subject of the appointment of a Medical Cholera Inspector, has, either through haste or inadvertence, expressed his question so obscurely that we are unable to comprehend its exact meaning.

Another Subscriber.—The paragraph is undoubtedly a puff, but cannot be identified with the gentleman whose name is mentioned. We suspect the system is frequently pursued, but without evidence of its origin we cannot notice the matter.

Dr. Smyly.—Letter received too late for this number. It shall appear in our next.

Dr. Armstrong, Cork.—Advertisement received. We shall have pleasure in noticing the movement next week.

Dr. Hynes, Kinvara.—Nothing was further from our intention than to depreciate any candidate on religious grounds. We intend to revert to the matter next week.

Inquirer.—Answer in our next.

We are compelled to postpone a large number of communications, including the following:—Review of the Public Health of the Summer Quarter, Sir H. Marsh on Spasm of the Glottis, Dr. Banon's Introductory Lecture, our own observations on Mr. Ellis's Introductory Lecture, Dr. Drennan's Address to the Ulster Medical Society, Opening Meeting of the Obstetrical Society of Ireland, &c. &c.

Communications, &c., received from Mr. J. Holt Dunn, Westbourne Park; Dr. Oppert, Bloomsbury; Mr. W. J. Walworth, Dr. M., Southampton; Dr. Hearne, Dr. Shannon, Dr. Mitchell, Mr. G. S., Dr. Drysdale, Dr. Hynes, Kinvara; Dr. Wilson, Huddersfield; Dr. Beamish, Cork; Dr. Pierce, Newcastle; Dr. Davison, Dr. O'Mara (enclosure), &c.

Appointments.

EVANS, GEORGE, Esq., Senior Surgeon to the Marylebone Dispensary, has been elected Surgeon to the Hospital for Diseases of the Throat.
BANKART, J., M.B., F.R.C.S.E., has been appointed Surgeon to the Metropolitan Free Hospital, Devonshire-square, E.C.
CRUCKNELL, H. H., M.B., M.R.C.P.L., has been elected Physician to the Royal Infirmary for Diseases of the Chest, City-road, E.C.
FENN, E. L., M.B., L.R.C.P., has been appointed House-Physician to King's College Hospital.
ELLIOTT, Dr. Southsea, has received the appointment of Surgeon and Agent of Sick and Wounded at Southsea and Langston Harbour.
DAVIS, JOHN, M.R.C.S.E., has been elected President of the Sunderland Medical Society for the ensuing year.
DIXON, W. H., M.D., has been re-elected Librarian of the Sunderland Medical Society for the ensuing year.
ELLISTON, G.S., M.R.C.S.E., has been appointed House-Surgeon and Secretary to the East Suffolk Hospital, Ipswich.
HUSBAND, H. AUBREY, M.B., M.C.Edin., M.R.C.S., Lond., to be Assistant Medical Officer to the City of London Lunatic Asylum, Stour, near Dartford, Kent.
LITTLEWOOD, J., M.R.C.S.E., has been appointed Surgeon to the General Hospital, Nottingham.
YELD, H. J., M.D., has been re-elected Treasurer and Secretary of the Sunderland Medical Society for the ensuing year.
FREEMAN, D., M.R.C.S.E., has been appointed Medical Officer to the Village Hospital, King's Sutton, Oxfordshire.
STRANGE, A., M.R.C.S., Ed., has been appointed one of the Assistant Medical Officers to the Gloucester County Asylum.
WRIGHT, J. H., M.R.C.S.E., has been elected Surgeon to the Halifax Infirmary, vice T. H. Cresswell, M.R.C.S.E., resigned.
BURNE, J. G., L.K.Q.C.P.I., M.R.C.S.E., late Medical Officer of the Grand Canal-street Dispensary, has been elected third Surgeon and Physician to the South Dublin Union Hospital.

Vacancies.

POOR-LAW MEDICAL VACANCIES. ENGLAND.

Kirkby Moorside Union.—Dr. Chapman has resigned the Union; area 58,631; population 5739; salary £48 per annum. Also the Workhouse, salary £9 per annum.

Medical Diary of the Week.

WEDNESDAY.—Hunterian Society.—7½ p.m. Council.—8 p.m. Dr. Hughlings Jackson, "On a Case of Abscess of the Brain."
— Microscopical Society of London.—8 p.m.
— Literature, 4½.—Meeting of Council.
— Geological, 8.

THURSDAY.—Harveian Society of London.—8 p.m. Debate "On Cholera."
— Chemical, 8.—"Specific Gravities of Heterogeneous Liquids," Dr. Sprengel; "Gradual Verdation of Organic Bodies," Messrs. Chapman and Thorp.
— Mathematical, 8.—Annual General Meeting.

SATURDAY.—Metropolitan Association of Medical Officers of Health.—7½ p.m.
— Horticultural, 3.—General Meeting and Lecture.
— Botanic, 3½.

BOOKS, &c. RECEIVED.

Epidemic Cholera. By Dr. Camps. London: H. K. Lewis.
The Tropical Resident at Home. By E. J. Waring, M.D., F.L.S. London: John Churchill and Sons.
On the Endoscope. By Christopher Heath, F.R.C.S. London: John Churchill and Sons.
Temperature in Acute Disease. By Thomas Armetriding Compton, M.D. London: John Churchill and Sons.

ERRATA.—In Dr. Grimshaw's paper on "Typhus Fever" in our last, p. 462, line 5, for *Green* read *Graves*, and for *Nolan* read *Stoker*.

THE DIRECTORS OF

The General Apothecaries' Company

(Limited) beg to announce that they have purchased the old-established Chemists' business situated at

27, BISHOPSGATE-STREET WITHIN,

where (as at their chief Establishment in Berners-street) the purest Drugs and Chemicals may be obtained.

Extensive Laboratories, fitted in accordance with the most approved plans, enable the Company to supply all new preparations; whilst the addition of the requisite Drug Mills ensures for all *powders* (which are invariably ground on the premises) the greatest possible purity.

The Directors beg to state that at their City Dispensing Establishment as above, the greatest attention is paid to the careful and accurate dispensing of Physicians' and Surgeons' Prescriptions, the same principles having been adopted in the supply of pure Medicines, &c., which have already gained for the Company (both at the chief Depot at the West-end and at their established Branch in Liverpool) the confidence and appreciation of the Medical Profession.

London Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

LECTURE,
INTRODUCTORY TO THE SESSION,
DELIVERED IN JERVIS-STREET HOSPITAL,
DUBLIN.

By A. BANON, Esq., M.D.,

VICE-PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS.

GENTLEMEN,—In meeting you in this theatre on the opening of the Session, I deeply feel the importance of the occasion, and the responsibility which attaches itself to me as well as to yourselves, in commencing our work of Clinical Instruction. When I consider that on the manner in which this instruction will be imparted to you by the physicians and surgeons of this hospital may mainly depend the amount of benefit you will receive during the ensuing Session, I cannot but feel anxious that any words I may address to you should be such as to convince you that, without close attention to the opportunities for the study of your profession which are opening before you, you will never attain that knowledge which will alone enable you to practise it with success. The time devoted to your hospital duties will hereafter be reckoned by you as perhaps the most profitably spent in your lives, and if now wasted or squandered in idle amusement, you will learn in after life that it cannot be compensated for. I would say to you, then, get into harness at once and encounter manfully the difficulties of the road you have entered on, and if you find its passage rough and weary at first, remember that it leads to success, and as you proceed with persevering industry all its difficulties will vanish before you. Before glancing at the nature of the studies which will specially be brought under your notice in this hospital, let us for a short space turn our attention to the nature of the sciences of medicine and surgery, and to the objects for which they are cultivated. The former may be said to consist in the knowledge of such causes as tend to the creation or production of disease, and of the means whereby it may be removed or averted; the latter in applying that knowledge to the benefit of man. It is to the acquisition of this knowledge that so many noble lives have been devoted both in ancient and modern times, and for which we all are now here assembled. The decided and rapid progress which both medicine and surgery have made in recent times can only be understood by looking back to remoter periods, and comparing what was then known with the discoveries of the present day. Of such importance were the sciences of medicine and surgery considered in the early periods; that divine honours were sometimes paid to those who made them their study; and if we look back to the works of such men as Hippocrates and Galen, we will find abundant evidence of their labour and research, and of the high estimation in which they were held. Without dwelling, however, on the history and lives of the great fathers of medicine, it will be sufficient for us to know that greater additions to our knowledge have been made within the last few years than during the centuries which elapsed from the times of Galen down to those of Harvey, the discoverer of the circulation of the blood. People in those times were too prone to take for granted the dogmas of the ancients, and slow in thinking for themselves; but a new era was to commence, and the labours of Harvey, Anbrose Paré, Petit, Le Dran, Chepelden, Malpighi, Haller, Pott, Morgagni, and many others, shed a new light on medicine and surgery, and advanced to the dignity of a science that which was before considered but as an art. At length came the great John Hunter, to whom

physiology and surgery owe so much; and here let me say that the study of the lives of these great men will well repay the medical student, teaching him the inestimable value of self-reliance and persevering industry, and also affording him an agreeable relaxation from his severer studies. Above them all stands the life of John Hunter, whose praises have been sounded in so many orations. A raw youth, first coming to London in 1748, he at once commenced the study of anatomy in his brother's school, investigating and thinking for himself on every subject connected with his profession, and finally mastering them. Subsequent investigations have, no doubt, dispelled errors into which he fell, and added much to the knowledge he imparted to us; but to this great man's labours we must look as affording us the starting points of many of the improvements in various branches of our profession, which have raised it to that height it now happily occupies (hear, hear). Can anything, gentlemen, be more noble than such a life? It will take you but a short time to read it, but it will take you years of patient labour and study to master the great ideas he has left us in his undying works, and illustrated by his unrivalled museum. To follow in the footsteps of Hunter, even at an humble distance, will be your duty. Learn first, as he did, something of the wonderful mechanism of the human frame, and of the laws which regulate its action during life, and by-and-bye you will be enabled to apply the knowledge you have acquired to the objects we should all have so much in view—of rendering our profession a real blessing to our fellow-creatures, and creating for ourselves a place in the respect and affections of our patients not to be gained by the followers of any other profession or calling. Remember that the sole purpose for which we are assembled, and for which parents may have made sacrifices to send some of you here, is simply that we may learn how to treat disease—that we may become worthy members of that noble profession to whose care the health of this wonderful work of God, man's body, is entrusted—that whether we see it stricken on the fever bed or writhing on the table of the operator, our knowledge of that profession may enable us, if not always to stand between it and death, at least to afford to it comfort and relief. I say we, for are we not all students together (hear, hear)? Not the most learned physician or surgeon can say he has learnt all; far from it, all of us must be students, many humble ones, to the last. Such was Hunter from the moment he entered his profession till his sudden death, nearly half a century afterwards, whilst attending his hospital duties; such it is the duty of every one of us to be, contributing as best we may to the progress of knowledge and the exclusion of error from a profession of which Sir William Fergusson truly says:—"It is hardly possible for the young mind to estimate or realise its magnitude or interest. Its influence extends over the whole human race, over every animal subservient to man's use or benefit; and from the lowest grade of man in savage life to the sovereign ruler over millions in the highest state of civilization, it is held in the greatest respect. There is, perhaps, no single occupation or profession amongst our social arrangements which has such an influence on individual man; and whilst it in some degree sways the daily actions of every one, it is equally felt by the masses. It influences alike the inmates of a cottage and those of a palace. To what, it may be asked, is all this to be attributed? The answer is simple. Medicine has the charge of the health of the living frame. There is no gift which the Almighty has bestowed on man equal to that of health. Without it the greatest intellects must be enfeebled, and it is in the mortal nature of man, even with his superior mental endowments over other animals, to place health as the foremost blessing of life. When are we impressed with the meaning of health, we fully understand the magnitude and grandeur of the objects and aims of medicine." Can I say anything more to induce you, gentlemen, to regard in their true light the importance of those aims and objects which should guide you in the pursuit of medical and surgi-

cal knowledge? To this purpose you will attend the dissecting and lecture-rooms, where gradually will be revealed to you the astonishing perfection of those organs of which the human frame is composed. Look to it in detail; the hand, the foot, the eye, the ear, the muscles and joints, the nervous and circulatory systems, and, in fact, any set of organs you may select. See the perfection and arrangement of their mechanism, so admirably suited to the functions allotted each of them to perform. See, examine, and admire them, and then, with Sir William Fergusson, attempt to realise the fact that all these wonderful triumphs of design and art are joined together in that frame which it is the object of all our study so to understand, that, when affected by disease, we may be able, by our acquired knowledge, to restore it to that health and perfection of action with which the Almighty originally endowed it. Physiology will tell us of many of the laws by which that action is regulated, and, as investigations proceed in this science and that of chemistry, no doubt many new and startling discoveries will be made; but let not the physiologist or chemist assume, and but few indeed have dared to do so, that life is nothing more than the development of that physical action the nature and laws of which these sciences have done so much to explain. The mind of man can never fathom the mystery of life, further than that it is the moving principle, set to work by an omnipotent hand, of all those wonderful functions and phenomena presented to our view in the animal and vegetable kingdoms. These are His works, and it is to our care the noblest of them all is entrusted. Let us see, then, how best we can go about understanding the important task which is before us. In the lecture-room, the dissecting-room, and the hospital lie your opportunities. In the former, the knowledge you will obtain in the sciences of anatomy, physiology, and chemistry, will enable you to understand the various deviations from the healthy state, or, in other words, the different diseases to be met with in your hospital. The advantages and facilities which will be here afforded I shall by-and-bye shortly allude to, and shall now say a few words on the present position occupied by medicine and surgery. The state of these sciences at the present day may well excite in us an amount of pride and admiration. No matter where we look, we see men of genius and indomitable industry investigating anatomy, physiology, chemistry, medicine, pathology, and surgery, with such success that new discoveries constantly reward their efforts; but still, gentlemen, the field remains not only open, but a void has yet to be filled up, without which it must be acknowledged that our knowledge of medicine is not alone imperfect, but fails most signally in affording us a true system of therapeutics. As yet we are obliged to practise, to a great extent, empirically, and must do so until by the light of science the various changes and physical actions occurring in disease may become so well understood that the cause of deviation from healthy action will be detected, and the required remedy pointed out. Until of late years medical men were too prone to take for granted the dictum of some great authority as to the treatment required by a particular disease, and even now there are many of us too much influenced by the same inclination. Our predecessors having thus failed in giving us what we most require, we must look to the present state of science, and let us see if it has as yet done anything towards it. Before quoting a recent experiment by Dr. Bence Jones and M. Dupré, mentioned in a recent publication by Dr. Cheadle, I would remind you that our acquaintance with specifics for disease is very limited, and amongst the most undeniable stands quinine for the treatment of ague.

"Dr. Bence Jones and M. Dupré have, by means of the spectrum, found that a substance which closely resembles quinine exists as a normal constituent of the human body. Starch, sugar, and albuminous products, are known to be common to both the animal and vegetable kingdoms; but this, if it prove to be quinine, will be the first powerful

remedial agent which has been discovered naturally existing in the animal tissues. Quinine is one of the very few specifics we possess, and should the discovery be confirmed by further observations, and we can learn how its excess or deficiency affects the economy, one link in the chain we seek will be secured, one great step towards a positive system of medicine will have been accomplished." It may appear strange that, notwithstanding the labours of such men as the Hunters, Bailly, Jenner, Læunec, and many others, whose equals we can rarely hope to see again, the principles of the treatment of disease should be still of so uncertain a character that this all-important branch of our profession may be said to be almost as yet in its infancy. From the researches at present going on by Dr. Bence Jones and others, it would appear that the right road has at length been taken, and that the addition of such facts to our present state of knowledge as those I have just mentioned will afford us such light as will supply the great want of medicine, of an unerring system of treatment derived from science alone. Then, but not till then, will medicine be ranked above all professions, either as regards its scientific perfection, or the magnitude of the blessings it will enable us to confer on man. Much has in latter years been added to our knowledge of medicine and surgery; hygienic arrangements are better understood, and old nostrums and systems of treatment, proved to be injurious, are exploded. Who will now, except in rare exceptional cases, bleed in pneumonia or fever? I well recollect, when a pupil in this hospital, the number of patients bled every morning in the wards and dispensary for various diseases. So rare is now the practice, that you will be fortunate if, during the ensuing six months, you have even one opportunity of learning practically the simple operation of phlebotomy. Many attribute this revolution in practice to a change in the type of disease, and, most probably, to a great extent they are correct; but it is also undeniable that the nature of morbid actions is now better understood, as also the tendency of many of them, if uninterfered with, to return of themselves to the healthy state. Thus, in the treatment of fever, the exanthemata, and other diseases, we know from experience that certain changes and symptoms will occur, and that the poison producing them will at length be eliminated from the system by the unaided powers inherent in itself. Our duty, then, will be, in such cases, not to meddle too much with our nostrums or medicines, as was formerly the practice, but to stand by nature when her powers are flagging, and to apply all the resources of our art to restore the functions of the vital organs when endangered in the progress of the disease. To Drs. Graves and Stokes of this city the profession of medicine is much indebted for many improvements, and that concerning the treatment of fever in particular has commanded the approval and attention of most modern physicians. Graves taught the necessity of wine and other stimulants in certain forms and stages of fever, and Stokes followed him, regulating the practice by the state of the heart and general circulation. These men, I am proud to say, have raised not a little the reputation of the Irish school. In Dr. Beatty's eloquent address to the students of the City of Dublin Hospital last year, he thus quotes the opinion of the late Dr. Graves held by the celebrated Trousseau of Paris: "As Clinical Professor of Medicine in Paris, I have incessantly read and re-read the work of Graves. I have become inspired with it in my teachings, I have endeavoured to imitate it in the book I have myself published in the clinique of the Hotel Dieu; and even now, although I know almost by heart all the Dublin physician has written, I cannot refrain from perusing a book which never leaves my study; there is not a day that I do not, in my practice, employ some of the modes of treatment which Graves excels in describing with the minuteness of the true practitioner; and not a day that I do not thank, from the bottom of my heart, the Dublin physician for the information he has given me." This tribute, from so celebrated a man as Trousseau, to one whose friendship in earlier

years I had the honour to possess, and whose talents I so much admired, you will not, I am sure, think here out of place. The names of those men, and many others who have raised the character of the Irish school, will shortly become familiar to you, as will also those connected with the London, Continental, and American schools, who by their labours have elevated the sciences of medicine and surgery to a position never previously attained, by establishing true views of disease. It will surprise you when you come to see how many false notions and prejudices have been exploded; how, by the aid of the microscope, the laryngoscope, the ophthalmoscope, and the endoscope, investigations are being made of structures and diseases in parts previously hidden from our view; what improvements have taken place in our means of diagnosis; how men like Addison and Bright have had each a disease called after himself, from being the first to describe its symptoms; how, in surgery, the improvements in several operations, such as those for hernia, amputations, Amusat's operation for false anus, tying of arteries, acupressure, recently invented by Simpson, and that other triumph of the Dublin school, the treatment of aneurism by compression, have so materially advanced our knowledge of this branch of our profession. I may here allude to a formidable operation which has but latterly been admitted by surgeons as a recognised proceeding. I allude to ovariectomy, or the extirpation of an ovarian cyst. By the labours of Clay, Tyler Smith, Spencer Wells, Baker Browne, and others, the mortality from this operation has been reduced much below that following many of our other recognised capital operations; but still the question arises whether an operation attended with such risk to the patient's life should be advised or undertaken by a surgeon, unless in cases where the disease of the ovary is likely to be attended with danger to life. The success which has attended this very formidable operation in London has been most remarkable. But few cases have been operated on in this city, some of which were signally successful, and others rapidly fatal. In this hospital you will have opportunities of witnessing most of the capital operations from time to time. During the past year two operations of very unusual occurrence were here performed by my colleagues, Drs. McDonnell and Tyrrell. I allude to trephining the spinal column in cases of injury of the cord from fracture or displacement. The first of these operations was undertaken with the consent and advice of the celebrated physiologist, Dr. Browne Squard, who happened to be in Dublin at the time. Although no recovery, or any very permanent benefit followed in either of these cases, and, to my mind, it is doubtful whether such an operation should be repeated, still it is due to my worthy colleagues to say that nothing could be more brilliant or successful than the manner in which both were performed, eliciting from all present the warmest admiration.

The arguments for and against this proceeding have latterly been much discussed by surgeons, and you will find an able paper by Dr. R. McDonnell on the subject, in a recent number of *The Dublin Quarterly Medical Journal*, in which he discriminates the cases in which he recommends an operation from those in which any such proceeding is inadmissible. I have myself made and assisted at several post mortem examinations of cases of fracture and displacement of the spinal column, and in all of them the injury extended to the body of one or more of the vertebræ. Instances, however, do not unfrequently occur in which the injury is confined to the posterior arch, by which a portion of it is driven in on the cord, causing more or less complete paralysis and anæsthesia. Were we able during life to fix the limit of the injury to this portion of the spine, the temptation to operate for the purpose of elevating the depressed portion of bone would be great, but unfortunately we are seldom able to do so, and when the fracture extends to the body, for obvious reasons such an operation would not necessarily relieve the cord from pressure. I cannot avoid here saying, that I feel it a high

privilege to have been associated in this hospital with colleagues, all of whom are men not alone devoted to their profession, but who have, many of them, done much to advance our knowledge of it. Here Sir Dominic Corrigan first established that character as a physician which has elevated him to the high position he now occupies in this city. It was whilst physician to this hospital his observations were made on the nature of the sounds of the heart, and of cirrhosis of the lung. Here, when a pupil, I saw our senior Surgeon, Mr. O'Reilly, tie the subclavian artery in its first stage, an operation, the particulars of which, and the admirable manner in which it was performed, are now as fresh in my recollection as when, many years ago, as the pupil who had charge of the case, I gave the details to the late Dr. Flood for publication in his admirable work on anatomy.

The great depth of the position of the artery, its close proximity to the vena innominata below, embraced as it were between the common carotid artery and the internal jugular vein, with the par vagum in front, and the recurrent laryngeal and pleura behind, formed a combination of difficulties which a true anatomist and surgeon could alone surmount. This formed the fourth of the eight cases in which this, the most difficult operation known to surgery, has been performed—all of them having proved fatal, mostly by secondary hæmorrhage, owing to causes which the most expert surgeon cannot guard against. The experience of this operation, which these results have given us, will no doubt in future deter most surgeons from having again recourse to it. To Mr. Stapleton, as well as to the other physicians and surgeons of the staff, we are much indebted for valuable clinical instruction. The former's practical remarks on syphilis, and his translation of the observations of Ricord, you will find well worthy of attention. He was also one of the first surgeons who successfully treated varus or club-foot in this city. To Professor Hughes we are indebted for the benefits conferred on practical surgery by his modifications of Liston's and Dupuytren's splints, by the former of which all the indications for the successful carrying out of extension in oblique fractures of the femur are fulfilled—namely, the steadying of the splint in the vertical direction, the prevention of either eversion or inversion of the foot, the relief of the heel from pressure, the non-interference with either the sound limb or bedding, the non-necessity for a too frequent adjustment of the retentive apparatus, the power of varying the irksome position of the limb, and finally the facility of introducing the bed pan when necessary, are perfectly accomplished. The advantages on the other hand of Mr. Hughes' adjustment of his foot board to Dupuytren's splint in the treatment of fractures of the lower end of the fibula may be thus summed up:—

1st. The foot and fibula are steadily maintained in their normal relations.

2nd. The splint is prevented from becoming displaced by ascent, or in any other direction.

3rd. The heel is preserved from pressure.

4th. The extending force can with the greatest ease be increased or diminished and the foot board reversed.

5th. The apparatus is no way irksome to the patient, and as it demands but very occasional re-adjustment, it saves the surgeon a great deal of time, trouble, and anxiety; thus accomplishing, in a very simple, yet efficient manner, with Dupuytren's splint, even more than its distinguished inventor sought for in the treatment of fractures of the fibula.

Another operation, performed several times with success by myself in this hospital during the last few years, it may be well shortly to notice. I allude to that for the cure of vesico-vaginal fistula—an operation principally devised by Drs. Bozeman and Marion Sims, American surgeons—for the cure of that loathsome affection, which, though seldom endangering the life of the sufferers, renders existence almost a burthen to them. I well remember, in my pupil days, the annoyance frequently expressed by that excellent and benevolent surgeon, the late Abraham Colles, at

the failure of his many contrivances for the cure of this affection. For myself I will say that I look back with much pleasure to the results obtained by me in about fifteen cases operated on in this hospital, notwithstanding that their treatment was attended with much trouble and expenditure of time. I would be indeed ungrateful were I not to say how much of my success I owed to my friend Dr. Beatty, as well as to my colleagues in this hospital, for the valuable assistance they afforded me in several of the most difficult of these cases. My sole object, gentlemen, in at all alluding to the part I have taken in the treatment of this affection, is to direct the attention of the profession to the almost certain means now placed within our power of completely relieving these poor sufferers from a condition which, as I before said, deprives them of all the comforts of existence, rendering them loathsome to themselves and others. For the information of the younger students it may be well to say that these fistulæ generally follow sloughing of the vesico-vaginal system, or the injudicious use of instruments in tedious labour. The symptoms following this lesion are a constant dribbling of the urine through the fistula from the bladder, which has lost all power of retaining or expelling it, and the excoriation of the vagina and thighs from the constant contact of the urine, giving rise to much distress, and to a strong urinous smell from the person. Sometimes these fistulæ are of very large size, others are so small as to be merely "pin holes," but still giving rise to the same train of unpleasant symptoms. For the cure of the latter form of fistulæ I have devised an instrument, delineated in the paper I published on the subject last year, which much facilitates the principal difficulty of the operation. For a more full description of the operation, and the history of several of the cases treated by me in this hospital, I would refer you to that paper published in *The Dublin Medical Quarterly Journal* for February, 1865. I alluded just now to the Dublin method of treating external aneurisms by compression, and as in the wards of this hospital there are at present two patients undergoing that treatment—one a case of traumatic aneurism of the radial artery, and the other one of popliteal aneurism, you will have at once brought under your notice the principles on which this brilliant improvement in surgery are founded. It is truly termed the "Dublin method," for although for a century previously pressure in various forms for the cure of aneurism had been practised, the principles on which the practice was founded were erroneous, and therefore mostly unsuccessful, until Dr. Todd's cases in the Richmond Hospital in 1820 and 1825, followed by a case treated by Dr. Hutton in the same hospital in 1842, laid the foundation of an advance in the surgical treatment of aneurism, which is now universally regarded as one of the most important improvements of our art. To the late Dr. Bellingham, of this city, is mainly due the credit of establishing this treatment on a firm basis. It would occupy us too long to allude further to the improvements and discoveries which are of such constant occurrence in both medicine and surgery, but a passing allusion to the benefits conferred on us by the use of chloroform and æther may not be out of place. A few days since some of you here saw a patient so worn out by long-continued painful disease, that he gladly submitted to amputation of the thigh, close to the hip joint. So completely was he rendered insensible to pain by the administration of chloroform, that when the operation was completed he was not aware that it had been even commenced. Such cases you will frequently see in this hospital, and can you avoid exclaiming that the profession in which such things are done must be the noblest of all? The present age, as we know, teems with scientific triumphs, many of them of the vastest importance to man. Witness the electric fluid brought into subjection by the intellect with which man is endowed by the Creator, traversing the simple wires over the mountain and the desert, and under the bed of the vast waters of the ocean, and conveying in a moment of time our thoughts and desires from one hemisphere to the other! Can even this be compared with the

discovery of agents placing within our reach such positive benefits as we derive from chloroform and sulphuric æther, in rendering our patients insensible to that pain and anguish we all dread so much, which our nature so instinctively shrinks from, and which, in the practice of our profession, we are so often obliged to inflict. To the genius of Sir Humphrey Davy we owe the suggestion in his experiments on the nitric oxide gas, which led, nearly half a century afterwards, to the inhalation of sulphuric æther for relieving pain, first applied by an American dentist in 1844, and improved on by the substitution of chloroform in 1847, by Dr. Simpson. I fear, gentlemen, I may have detained you too long in adverting to matters which you may perhaps better understand from books, and that some of those subjects I have mentioned may be puzzling to those of you who are here for the first time. I would therefore recommend the first year's student, while not dismissing them from his mind, to defer their consideration until he has mastered the more commonplace but not less important matters which will daily come under his notice during his hospital attendance. Watching the healing process of an ordinary sore leg, or even of a simple incised wound, will afford opportunities, which should not be neglected, of studying and meditating upon that vast page in physiology which treats of the wonderful reparative powers of nature. Amongst you there may be some destined to become distinguished members of our profession, and whose names may yet be ranked by a grateful posterity as eminent chemists, physiologists, or surgeons; but to the great majority of you a much humbler, but still an honourable and useful career, is open. With a fair knowledge of your profession, in its scientific as well as practical bearings, whether your lot be cast amongst the poor or the rich, you will be useful citizens earning the love and respect of those on whom your skill will enable you to confer inestimable benefits in their hour of trial. The opportunities which will be here open to you for acquiring a practical knowledge of medicine and surgery you will find ample. A large dispensary attached to the hospital is daily opened. Surgical diseases and accidents requiring operation are of frequent occurrence. Two surgeons and one physician attend each morning, giving such instruction at the bedside as each case may suggest. One medical and two surgical lectures are delivered in this theatre weekly, and the more advanced and attentive amongst the pupils will be selected to dress and look after cases of importance. You will find the medical officers always ready to meet the inquiring student with the fullest information in their power. All they will ask in return will be attention and kindness to the poor patients on your part, and a gentlemanlike demeanour amongst yourselves and towards the estimable and charitable ladies who devote their lives to the care of the sick in this institution. For yourselves, you should select clean and comfortable lodgings not far from your hospital, which you should attend most punctually at the visiting hour; take full notes of every important case you may meet with, and be guided in your reading by the advice of your teachers. Arrange, if possible, to pass your first examination at least a year before the final one, in order that you may devote the last months almost exclusively to your hospital. Combine with your study healthful exercise and rational amusement, which, instead of retarding, will increase your power of obtaining knowledge. Do this, and you will return to your homes with your minds opened to the magnitude and grandeur of the objects of that profession you have chosen to embark in, and with an ardent thirst for further knowledge; neglect it, and what your fate may be it would be painful to contemplate; for, it is but too true, experience has shown that the character, for good or evil, which the student makes for himself during the early period of his career, will, in the great majority of instances, adhere to him through life. Commence, then, to establish your character by diligence in your hospital duties.

which, as Sir Benjamin Brodie tells us, "will soon be found, to those who desire to learn, replete with interest. At first all is confusion. The nice distinction of symptoms on which the diagnosis of disease depends, why the pulse in one case indicates immediate danger, and in another none at all, why one patient recovers and another dies, why the same kind of treatment is successful in one instance and fails in another; these, and a multitude of other matters are quite inexplicable to the young student. Everything is seen, as it were, through a mist. After no long time, however, the mist begins to clear away, and whoever has advanced thus far finds no difficulty afterwards. Every case is an interesting subject of inquiry. A great game is being played in which the stake is often neither more nor less than the life or death of a fellow-creature, and in which those among the students who devote themselves to their business perform an humble, yet not unimportant part, without any painful feeling of responsibility." Weigh well, then, what you are about to undertake, which, though a life of labour and anxiety, rewards, as no other profession can do, the man who, by his acquired knowledge, is enabled to minister to the wants of his stricken fellow-man.

Hospital Reports.

ST. MARY'S HOSPITAL.

HYDROCELE AND ITS TREATMENT.

By Mr. HAYNES WALTON,

SURGEON TO THE HOSPITAL AND TO THE CENTRAL LONDON
OPHTHALMIC HOSPITAL.

(Continued from page 490.)

THE subject of hydro-sarcocele was then considered, and the definition given as being fluid collected in the tunica vaginalis, along with swelling of the testicle. It was an affection for the most part due to chronic orchitis, but may be attributed to other morbid changes—malignant as well as innocent. It usually was not difficult to distinguish this from ordinary hydrocele. The history of the case generally pointed to the difference. The size of the testis, and the tenderness of it, confirmed the disease. He warned his hearers not to treat hydro-sarcocele in the first instance as simple hydrocele, but to endeavour to cure the disease of the testis by general measures, when, in all probability, the hydrocele would go. If, however, after the testicle was no longer diseased the hydrocele remained, it should be submitted to treatment, and injection employed, as in any ordinary case. He advised them never to inject double hydrocele at the same time, because of the severity of the inflammatory action which might ensue, but to let a sufficient time elapse after the first was done, before attacking the other.

Hæmatocele was so much connected with hydrocele, that he deemed it prudent to consider it in the concluding portion of his lecture. It was swelling caused by effusion of blood in the tunica vaginalis, or in a cyst connected with the testicle. There were two varieties of hæmatocele—the first occurred in a natural state of the testicle, from the accidental rupture of a blood vessel, and so the tunica vaginalis got filled with blood; in the second, the extravasation took place when a hydrocele was present, and may be caused by a blow, or during the operation of tapping, when the testicle was either wounded, or a vessel that was wounded outside the tunica vaginalis bled within the cavity. The blood which was poured out acted as an extraneous body, and often caused acute inflammation of the tunica vaginalis. Sometimes it produced a chronic form of inflammation, invading the surrounding

fascia and connective tissue. The tunica vaginalis was apt to become very much thickened. In old hæmatocele the blood underwent several changes—sometimes it was broken up into a fluid, like coffee grounds; sometimes it was converted into a soft fibrinous substance, deposited in layers, and more or less decolorised; sometimes it was of a honeycomb appearance, infiltrated with reddish serum. He laid great stress on the fact that the testicle was in the same position as ordinary hydrocele, but subject to variations from the same causes; the testicle itself was apt to undergo more or less atrophy from pressure. The diagnosis from that of hydrocele was the absence of transparency by the light test, the heaviness of the tumour, and the obscure fluctuation.

The treatment of the first variety, if the hæmatocele was small, should be antiphlogistic; that is rest, the application of cold, and slight purgation. But if suppuration should ensue, or the effusion of blood be large, the sac should be opened.

In the second variety, if the quantity of blood be small, and mingled with the fluid of the hydrocele, tapping should be resorted to, and repeated if necessary till the blood disappeared. When, however, there is a great deal of blood effused, with acute inflammation of the part, and suppuration was dreaded, the tunica vaginalis should be opened and the blood got rid of.

Mr. Walton endeavoured to point out the importance of avoiding the testicle in this latter operation, and assured his class that except they proceeded with great care, remembering always how the testicle may in different cases be in different parts of the sac, that it was in danger of being wounded. Of course, if the tunica vaginalis were very thickened its position could not be accurately made out; hence the still greater care necessary in operating. In very large chronic hæmatocele, with considerable consolidation and thickening of the sac, in persons far advanced in life, our highest authorities recommended the excision of the whole of the mass, including the testis.

SPECIAL REPORT

ON THE

TREATMENT OF CHOLERA BY VENOUS INJECTIONS.

III.

THE EPIDEMIC OF 1848-9.

(Continued from page 466.)

DURING this epidemic the London Hospital threw open its doors to cholera patients, and seven cases, admitted under the care of Drs. Cobb and Little (who by this time had become full physicians to the hospital), were treated by injections of saline alcoholic fluids into the veins. Of these four died and three recovered, a result much more satisfactory than that of the cases detailed in the last section of this report, and which was no doubt partially due to the more favourable conditions under which the operation was performed. The patients had the benefit of all the resources of one of the largest metropolitan hospitals. Instead of being prepared under all the disadvantages of haste, large quantities of the fluids were kept ready in well stoppered bottles. Great care was taken to secure the liquid passing into the veins at a proper unvarying temperature, and instead of the syringes previously employed, an instrument designed expressly for the purpose by Dr. Little was used in all the cases. From its great simplicity this apparatus is easily used; it furnishes security against the admission of air into the vein, and the occupation of time necessitated in turning the taps, noting the temperature, and watching the effects of each succes-

sive syringeful injected, is looked upon by its inventor as a considerable advantage, since a too rapid injection has

been found injurious. The following diagram fully explains the use of this apparatus:—

Dr. Little's Syringe for injecting fluids into the veins.

A. Syringe with two apertures in the cock; one (B) communicating with reservoir; the other (C) leading to vein. D. Tube to introduce into vein connected *immediately* with cock. E. Body of syringe, brass, tinned inside, capacity about two ounces. F. Conical brass reservoir, silvered inside and coated with caoutchouc outside. G. Mercurial thermometer in ivory frame placed in the reservoir. A tap within reach of operator allows the fluid to pass from the reservoir to the syringe.

The fluid employed being in all the cases identical, we may first of all record its composition, which was as follows:—

℞ Sodæ hydrochloratis, ℥ij.
— sesquicarb. ℥ij.
Aquæ distillatæ, ℥cxxx. M.

This solution was carefully filtered. Immediately before injection it was heated to a temperature of 110° to 115° Fahr., ℥ij. of alcohol added to each imperial pint, and the whole carefully stirred.

Since the commencement of our Special Report a detailed account of the cases treated has appeared in the "London Hospital Reports." Only a brief abstract of them will therefore be given in this place, and first of all of the unsuccessful cases.

LONDON HOSPITAL.

FOUR CASES OF CHOLERA UNSUCCESSFULLY TREATED BY VENOUS INJECTIONS.

Case 7.—Malignant cholera; admitted in collapse at three P.M., having been seized with diarrhœa, vomiting, cramps, &c., at eleven A.M.; suppression of urine from that time. At six P.M. he was seen by Drs. Cobb and Little, when he appeared to be fast sinking into a hopeless state. Seventy ounces of the fluid injected into median-basilic vein; a second injection was afterwards attempted, but he sank rapidly.

Case 8.—Malignant cholera; admitted to the hospital at noon in a state of collapse, having been seized with abdominal pain and cramps at eight A.M. At one P.M. an injection of saline fluid with alcohol, to the extent of eighty ounces, was effected. The skin immediately became warm; the pulse previously imperceptible was now regular, 120; the lips from livid became red; the temperature rose from 85° to 90°, and the patient was able to speak distinctly. At three P.M. an immense rice-water evacuation; the pulse diminished in strength, and rose to 160. At half-past four P.M. vomiting and almost pulseless; seventy-four ounces of the fluid injected. He again improved greatly, and a little after five P.M. passed about three tablespoonfuls of urine. At eight P.M. was again sinking; one hundred and ten ounces injected; partial revival followed. Ten P.M. Pulse small and very quick; cold sweats. Eleven P.M. Nearly pulseless. Quarter-past eleven. Death.

Case 9.—Cholera in a woman admitted to the hospital in extreme collapse. At two P.M. twenty-five ounces of the fluid injected; as it caused great pain in *right* side

of chest, about the seventh and eighth ribs, Dr. Little thought it better to desist. He informs us that this is the only case in which he has witnessed any aggravation during the injection. She died about two hours afterwards, but no post-mortem was permitted by the relatives.

Case 10.—A mariner seized at midnight, and admitted to the hospital at a quarter-past six A.M., with malignant cholera. Collapse most rapid; nearly pulseless, and getting worse every minute; coldness universal; forty ounces of the fluid injected; copious perspiration ensued over face and neck; he lay much easier, the colour improved a little, and the temperature under the tongue rose from 78 to 86°; nevertheless, he died about an hour afterwards.

The above are the four fatal cases that were treated in the London Hospital at this period. By way of comparison, we may add to these a case injected in private practice, under Dr. Little's care, during the same epidemic.

Case 11.—A young lady having taken a calomel and colocynth pill for constipation, was seized with cholera the next morning; visited at noon by Dr. Little; at six P.M. collapse was complete, and death seemed near at hand; sixty ounces of fluid injected between seven and eight P.M.; pulse returned; face and surface became warmer, and she expressed herself as better, and as relieved from the oppression of breathing and epigastric pain; vomited once. At eleven P.M. had again become collapsed, and purging returned; thirty ounces more of fluid injected with similar relief, but less marked than at the first operation; amelioration continued till after midnight. A third attempt to inject was made by the gentleman in charge, but the patient sank before the completion of the process.

In this case the difficulty of carrying out the treatment by injections in a private house was found considerable, although the house being that of a chemist, this difficulty was less than usual. Undoubtedly the treatment is more easy, and so more likely to be successful in an hospital.

Having thus recorded the fatal cases of the epidemic of 1848-9, we propose now to review the four instances of recovery under this treatment which, as already stated, took place at the

LONDON HOSPITAL.

Case 12.—A seaman, aged 22, admitted August 13, at noon, under the care of Dr. Little. Had been attacked by vomiting and purging on the previous day. At five P.M. cold and pulseless; no urine passed. On the 14th no pulse had been distinguishable, either in radial or brachial arteries; no urine had passed; tongue 82° F.; most profound collapse. His colleagues deeming the case hopeless, Dr. Little resolved to try injection of his salino-alcoholic fluid. When ℥xx. had been introduced, the respiration was more frequent. After a pause ℥xx. more thrown in. The pulse became tolerably full at the wrists and temples. After ℥lxxx. had been injected, the breath was warmer; patient expressed himself relieved; perspiration appeared on forehead; skin above the eyebrows from inky blue became dingy red; pulse soft and full, 88. At 6:30 steady pulse,

increased warmth, and improved colour of surface proved that the power of generating heat had been resuscitated. At eight P.M. fifty-five ounces, and at midnight seventy ounces injected.

15th. Had vomited twice, and purged a black-greenish fluid; pulse, colour, and temperature maintained. In the evening, these failing, forty-five ounces were injected.

16th (9:30 A.M.). Sensible; slept little; tenderness over epigastrium; no headache; heavy-eyed, colour almost natural; injection of conjunctivæ; temperature of mouth 93° F.; pulse 96; says he has voided urine; has had two pints of milk and half a pint of sherry in the twenty-four hours; veins of natural fullness.

17th. Has had some sleep, and taken barley-water, ice-water, and beef-tea; veins moderately distended; has vomited and purged; pulse 72, weak; temperature of mouth 92° F. To take three grains of carb. ammon. in camphor water every two hours; a pint of milk and four ounces of wine in twenty-four hours. 4:30 P.M. Half a pint of urine voided apart from fæces.

18th. Aspect of a convalescent from cholera; pain in bowels; colour, temperature, &c., maintained; mouth 83° F.; pulse 72; motion and urine twice; a purulent discharge from right ear. To take carb. ammon. in infusion of bark; enema of six ounces of beef-tea every six hours.

20th. Pulse 84, fuller and stronger; a drop of pus from one of the incisions in the left arm; no sickness; urine, twenty-four ounces; one motion.

21st. Pulse 88; no motion; more urine.

22nd. Pulse 78, quick; three motions; removed to a more airy ward.

23rd. Pulse 78, full; tongue clean, moist, red, and smooth; three motions, all fæulent; urine free.

24th. Had enjoyed a basin of bread and milk last two days; "feels quite well, except weakness;" pulse 80, full, soft; respiration 18; temperature of tongue 97° Fahr.

From this date, the tenth day after operation, continued to improve.

On the fourteenth day of treatment he dressed himself. No looseness of bowels remained, and the incisions were healed.

He now took a mutton-chop, milk, beef-tea, and three ounces of wine.

A week later, on the twenty-first day of treatment, took exercise in the hospital garden, and all the functions were perfectly performed. He never had the slightest cough.

Dr. Little saw this patient on the 19th January, 1850, quite well, after having visited the United States and returned.

The urine voided by this patient on the 17th and 18th was carefully examined by Dr. Letheby, who found an enormous amount of extractive matters, alkaline sulphates, and an unusual amount of phosphates. Moreover, very small quantities of alkaline chlorides were detected, notwithstanding the quantities of salts injected. This was considered by Dr. Letheby, and will certainly be generally accepted, as "a strong indication of a great deficiency of saline matter in the blood" of this patient. The urine of the 17th contained much more extractives and sulphates, and much less urea and uric acid. In fact, on the 18th, the secretion approached much nearer to its natural qualities. Examinations of the secretions of cholera patients by reliable authorities are so scarce that we are glad to subjoin Dr. Letheby's minute analysis:—

	Urine voided on the 17th.	On the 18th.
Quantity voided,	3vss.	3vj. 3v.
Appearance,	dirty brown turbid liquor, looking like broth.	clear amber coloured liquid.
Odour,	putrid and very offensive.	not peculiar.
Deposit,	copious, of triple phosphate.	slight mucous.
Specific gravity,	1016.4.	1012.8.
Reaction to test paper,	very alkaline.	acid.
Albumen,	not present.	not present.
Sugar,	not present.	not present.

Solid matter in 1 fluid ounce,	6.6 grains.	10.2 grains.
Of which alcohol dissolved,	3 grains.	4.7 grains.
Solid matter in 1000 grains,	13.5.	20.8.

Percentage Composition of the Solid Residue.

	17th	18th
Urea	0.56	36.21
Uric acid	1.29	2.30
Extractive matter and mucous	54.20	30.56
Alkaline sulphates	30.31	16.61
Alkaline chlorides	.72	a trace merely
Alkaline phosphates	4.35	10.28
Earthy phosphates	7.57	4.12
	99.00	100.08

Case 13.—J. T., seized September 7, 1849, with dyspnoea, on the 8th with diarrhoea, on the 9th with vomiting. Admitted to the London Hospital, under the care of Dr. Cobb, at three A.M. on the 11th, in collapse with cramps; not pulseless; absence of urine.

At ten A.M., injection of thirty ounces of the fluid. During the operation pulse rose from 76 to 88, and became more distinct; pain and cramps left him. The temperature under the tongue rose from 89° to 91° F.; he said he was well and would like to get up; a relapse came on at 1:30, with vomiting, pain, and cramps; fifteen ounces more injected; vomiting abated, and he became more comfortable.

Eight P.M. Had slept a little; no urine passed nor purging during the day.

12th: Slept a little in the night; only vomited once; a liquid yellow motion at 4:30; about a tablespoonful of urine; pulse 96, full, strong; mouth 88° F.

One P.M. Pulse 102, full; had a motion at 11:30 of the consistence of gruel.

Eleven P.M. He vomited water tinged with bile, at 2:30, after which he slept; has passed about twelve ounces of urine; pulse 96.

13th. Bowels open twice in night and has been sick; enemas of beef-tea, and to take wine.

14th. Five motions; the last containing a large quantity of bile. He continued to improve up to the 24th, when he was discharged cured.

Case 14.—A blind vagrant, æt. 50, admitted to the London Hospital, under the care of Dr. Little, August 27, 1849, in incipient collapse; at first treated by calomel, but as the collapse only advanced for eighteen hours, he was injected to the amount of forty ounces. For many hours his condition remained evidently improved. There was absence of urine for from seventy to eighty hours, and blood passed with many of the stools. On the 30th, he passed a fæulent motion, without blood. Pulse was distinct, small, 96; abdomen tender. Hot-air baths, beef-tea per rectum, wine and water, brandy and water, milk, but no medicines, were prescribed.

Seven P.M. Better; pulse 90, fuller; no urine, but another motion, without blood.

31st. Passed urine twice; the first time, three ounces; the second, eight ounces; has had three fæulent motions; pulse 96, fuller, and stronger.

September 1st. Better; temperature and colour natural; urine twice; one motion. Discontinue enemas, and take milk, beef-tea, wine and water, yolk of egg, &c.

From this date he made a good recovery. He suffered from tenderness of abdomen for some days, which is not surprising when we consider the number of bloody stools passed—a symptom usually considered as justifying the worst prognosis. But our report of these cases has occupied so much room, that we must defer our remarks upon them.

A PHRENOLOGIST, one Dr. Rivoli, has discovered that Garibaldi's head shows unmistakable organs proving abnegation, prudence, sang froid, meditation, eloquence, loyalty, deference towards others, and perception of character.—[Phrenology is always accurate after the character is known.]

HARVEIAN SOCIETY OF LONDON.

October 18th, 1866.

Dr. THOMAS BALLARD, V.P., in the Chair.

Mr. W. SEDGWICK related a case of

UMBILICAL HÆMORRHAGE.

Which had lately come under his observation, in which the third child (a daughter) in the family of a mechanic in comfortable circumstances had hæmorrhage from the umbilicus on the ninth day after birth, and the sixth day after the separation of the funis. The hæmorrhage, which was considerable, was arrested for a time by long-continued and well-sustained pressure. There was a slight recurrence of the bleeding on the following day, which was checked by a renewal of the pressure, and the patient recovered. The first child in this family was full-grown and apparently healthy, but had been born dead. The second child, a daughter, died on the nineteenth day after birth from umbilical hæmorrhage associated with purpura, which began on the twelfth day after birth, the cord having separated on the third day. Both the parents in this case were young and healthy; but the family history on the side of the mother was unfavourable, for her father had died insane at the age of thirty years, and her mother had died in childbirth with her fourth child, leaving two sons and a daughter. The elder of these two sons died of fever at the age of twenty-seven, leaving two children, a boy and a girl, both free from disease; whilst the younger son, who is still living, has had occasional attacks of hæmoptysis.

A paper was read by Dr. HENRY MAUDSLEY,

ON SOME OF THE CAUSES OF INSANITY.

The author observed that it was almost impossible in many cases of insanity to assign any *one* cause as producing the disease; there was, as usual in such questions, a plurality of causes to be taken into account in each case. In this paper it was his design to treat not of the pathological causes of insanity, but of its predisposing and exciting causes. Civilization had been considered by many authors as a predisposing cause of insanity, but even here it seemed that there were some difficulties in arriving at any certainty, for, although there was said to be one in four hundred persons in civilized countries in a state of insanity, it was not possible to compare this fact with what occurred among savage tribes, because life was so short, and the weak succumbed so soon among such nations. There seemed certainly many causes at work in civilization not unlikely to cause aberration of mind. Of late years, in this country, there was certainly a great addition to the number of the insane in lunatic asylums. Thus, in 1865, there were no less than 29,425 inhabitants of lunatic asylums. There was, he believed, an evident augmentation in the proportionate number of lunatics in this country. One of the evident causes of insanity must be looked for in the fierce struggle for existence which now caused so many social wrecks to take place. The weaker and less able were trampled under foot, and thus ended their existence insane. A notable example of this was to be seen in the case of women; man had as yet taken the more lucrative employments as his prerogative, and left only the worst paid to women, who were thus confined almost entirely to the state of marriage, to secure anything like a certainty of existence. This was one of the most frequent causes of the breaking down of the mind in women. He did not think that self-abuse was a frequent cause of insanity in women but that it was rather one of the symptoms of the malady; among men, on the other hand, it was one of the common causes of insanity. The trivial and defective education of women left them quite unable to cope with the unfortunate position in which they

were so often placed. Overcrowding and the brutal degradation of the poorest classes tended to produce physical and mental degeneration, and this was well known to be the result of over population in old countries. Again, disease of all kinds of a lowering character in parents, such as consumption predisposed children to insanity. A great proportion of lunatics, too, died of tubercular disease. It was often observed that, when families were dying out, consumption, and insanity were frequent among the members. Speculation in business was a common cause, and the complete deadening and hardening of the emotions common among the commercial classes certainly tended to produce insanity among their offspring. Effeminacy and luxury also were in highly civilized countries conditions favouring insanity and deterioration of the race; they tended to produce a sort of cretinism, just as a similar condition was produced by bad air and water.

Hereditary predisposition had been very variously estimated as a predisposing cause, some authors believing that nine-tenths of those affected were thus predisposed, and others only one-tenth. In fifty cases examined by himself, it occurred in marked form in fourteen. Any form of nervous disease in the parents might dispose to insanity in the offspring. Thus epilepsy might occur in one member, and insanity in another. Inter-marriage, in his experience, was a frequent cause.

Intoxication was in this country by far the most common physical cause of mania and idiocy; sexual excesses came next. Mania might in some cases be vicarious with epilepsy. He had seen some cases of this kind. The puerperal state was sometimes a cause of mania, as also acute rheumatism and typhoid fever. Injuries to the brain from railway accidents, and other causes, were followed by insanity in some cases. As to moral causes, single women in some instances became violently devout and ended in insanity, whilst disappointed affection also might sometimes lead to a similar result. Great intellectual activity alone, he considered, did not lead to insanity; it was only when this was accompanied by some painful emotions, such as that of being distanced by some successful competitor, or that of being unequal to responsibilities.

Dr. CHARLES DRYSDALE, after remarking on the absorbing interest of the subject, one too little brought before the notice of medical men in medical societies, observed that there could be no doubt that the struggle for existence alluded to by the author, and so well explained of late years by Malthus, Mill, Darwin, and Huxley, was one of the great causes why insanity and consumption were now such common diseases. In former times wars and fevers crushed the weak; but now the long chronic maladies of consumption and insanity, &c., had taken their place, and would continue common until it was perceived that over population was the chief evil that the human race had to contend with. In the case of French statistics, epilepsy and convulsions was assigned as the most common cause of insanity; but he could readily believe that in this country drunkenness was the chief cause; and this pointed towards something being done towards rendering life in this country more artistic and less monotonous. The next commonest physical cause was sexual excesses, enforced celibacy, and self-abuse. All of these together caused a great amount of insanity, and Mr. Holmes Coote had said that there was no cause of insanity among the young of both sexes more common than the last of the three. The enforced celibacy of so many of the women of the better classes was most dangerous, too, he thought, for the maintenance of that balance of the intellect and emotions necessary to sanity. He quite agreed with the noble remarks made by Dr. Maudsley upon the subject of the position of women. When not maintained by relatives and compelled to receive wages, their wages were ridiculously low, in comparison to the amount of labour expended, to that of men; and as marriage, the only security they at present had in this country of a certain existence, was much fallen off in frequency, it was no wonder that they often became

desperate, and ended insane. Asceticism was a frequent cause of insanity, and the dwelling upon supernatural ideas, he thought, over much, tended in his experience to produce insanity.

Loss of friends, disappointed ambition, and love, were the next most common causes of what the author of the paper had truly called the social disease. The most common antecedent of all, however, was certainly hereditary transmission.

Dr. HUGHLINGS JACKSON, after briefly alluding to the great and obvious value of the author's contributions to our knowledge of disease, proceeded to remark on some points in the paper, chiefly with a view to show the different experience which he (Dr. Jackson) had obtained by studying diseases of the nervous system at a general and at a special hospital, from what those physicians practising in insanity had obtained by studying nervous diseases at asylums. He did not venture to speak critically of any part of medico-psychological science, as he had seen very little of cases of decided insanity. His remarks were, he said, intended to be general, and would, he feared, bear but indirectly on the important questions which the author had stated with such remarkable width and precision. He (Dr. Jackson) thinks that cases of what may be called coarse disease of the nervous system—*e. g.*, damage by blood-clot and tumours—and these cases are chiefly under the observation of those practising generally—ought to be carefully considered by medical psychologists, in order that they may obtain a knowledge of certain comparatively unimportant, and yet highly significant, symptoms, some of which evidently stand betwixt the two artificial extremes, which are conveniently, although arbitrarily, distinguished as physical and psychical symptoms. On the other hand, medical men practising generally, can scarcely give small signs of mental disorder wide enough relations. The progress of our studies of nervous diseases is, he (Dr. Jackson) believes, hindered from the fact that able and industrious men, practising in different departments, have not opportunities of working harmoniously as members of one scientific organization. There is, since the days when every doctor was a general practitioner, great differentiation, but not the higher nicety to which, as in organisers, this differentiation should lead. However elaborately our medical knowledge, acquired in different fields, may be arranged, it is still badly organised, and, indeed, some of the present arrangements of diseases, or of symptoms of disease of the nervous system are, he (Dr. Jackson) thinks, altogether subversive of true scientific method. Speaking of hereditaryness—still with the same general object in view—he (Dr. Jackson) thinks that the general question of transmission of disease requires to be studied with more width, and also with more precision than we now, according to our present divisions of work, possibly can study it. For instance, each in his own field of labour might study cases of nervous disease with regard to this question very minutely, but the too arbitrary division of our work into sections drives us to a narrow style of study, and thus our minuteness is not always precision, and our width tends to vagueness. The fact that a man had hemiplegia, and his wife epileptiform fits, is, he maintains, no certain evidence that their children will have a tendency to fits or paralysis. He conceives that the transmission is not so much of bad organs as of imperfect tissues, and that a child can scarcely be said to inherit a symptom directly, as for instance, convulsions of any sort, but rather degenerate tissues. The father's paralysis, to return to the illustration just given, would be due most likely to disease in the brain, as tearing up by effusion of blood of a nervous organ, usually the corpus striatum, and not to primary changes beginning in nerve tissue itself, for hemiplegia is nearly always due to cerebral hæmorrhage. The mother's fits may have followed syphilitic disease of the brain's membranes. Then their child if it becomes hemiplegic, or becomes liable to have epileptiform fits, cannot be said to have inherited a tendency to either of these *symptoms*, although it may be born with a tendency to degeneration of

tissues forming part of the vascular system, or with a syphilitic taint, which so often induces or allows disorderly growth in a low vegetal tissue. Whilst it is not rare for grandfather, father, and son to suffer hemiplegia from cerebral hæmorrhage, the grandson can scarcely be said to have inherited this kind of paralysis, but rather to be born with his family's tendency to wide degenerative changes, of which disease of the blood vessels is nearly always one part, and the changes of chronic Bright's disease very often another. A fresh illustration: a child is born liable to those tissue changes which constitute tuberculosis, and dies when grown up, as many of its immediate relatives died of tubercular disease of the lungs; but it would not be generally held that a tendency to disease of an *organ*—the lungs—was transmitted. No one ventures to say that tubercular meningitis in children is hereditary, although several of a family may die of this disease. For tubercle in children is nearly always widely scattered, and very rarely indeed affects one organ only. It will, however, he said, not be fitting to be too dogmatic on such points, as the distinct relations of tissues, organs, and functions are not sharply defined, as may be seen in the dawn of that part of the life of the world which we call organic, and these three things are inseparable in life. What he denied in one way he might be accused of admitting in another. A child may inherit feeble nerve tissue, and thus *indirectly* a tendency may be transmitted to a *class* of nervous diseases, not to *any* nervous diseases. It is, then, he (Dr. Jackson) conceives, most important to try to distinguish in all nervous diseases or symptoms—from the simplest, such as paralysis of the third nerve, to the most complex perversion of the highest function of the brain—whether the pathological alterations be primarily of nerve tissue or be secondary changes of some inferior tissue which helps to make part of nervous organs. In cases of paralysis of muscles supplied from a single nerve trunk the nervous elements of the bundle may suffer (1) from disease of the areolar tissue about it, as from syphilitic disease, or (2) from wasting of the true nervous elements, as most likely occurs in the amaurosis, &c., which now and then happens in locomotor ataxy. This distinction leads to one of three natural orders of all diseases of the nervous system, or rather of our thoughts on disease—one of three, as there are two other orders—*viz.*, (2) according to damage of organs, and (3) according to disorders of function. Each case of disease ought to be considered as it bears on each of these three lines of thought. Roughly speaking, there are, from the tissue changes point of view, two classes of nervous diseases. The first class includes those *essentially* nervous—*i. e.*, those due to changes beginning in nerve tissue itself—and possibly the intimate changes in the brain giving rise to or permitting many forms of insanity are faults of this tissue; the second class includes diseases in which nervous tissue is indirectly affected, as when hemiplegia occurs from rupture of blood vessels in the corpus striatum, or when epileptiform fits or amaurosis (or, more precisely, the minute changes on which the last two signs of disordered or lost function depend) follow some time after coarse disease of the connective tissue of the pia mater (such as syphilitic "deposits") has been well established. To put the whole again, and more widely: Parents transmit tendencies to disease of the nervous skeleton, or of the connective tissue skeleton, or (and this is speaking very loosely) of the arterial skeleton. Instead of saying, "to transmit a tendency," &c., it may perhaps be better to say, transmit an imperfectly developed tissue or tissues; but the expression "tendency" is better in this way, that it has not enough meaning to carry a theory, and is used as a mere verbal artifice, not so much of science as of language. Here it is proper to add, that the above remarks are, in principle, but an application of much wider doctrines long ago taught by Laycock. A feeble, nervous skeleton being transmitted, only those diseases which depend on primary changes, slight and yet wide-spread, in nervous tissue itself,

would be likely to occur in both offspring and parents. These changes would be (as a matter of fact) of the cerebral hemispheres, because, although there are nerves in all parts of the system, this part of the body is made up nearly altogether of nerve tissue, and thus (a gain, as a matter of fact,) various disorders of the function of the chief nervous organ, constituting insanity, and perhaps some forms of epilepsy, would occur in several members of one family. Among those of the first class of diseases would be a certain kind of atrophy of the optic nerves, progressive diseases of the nervous system in general, and probably certain forms of insanity. The *idea* is the same, whether nerve tissue is wasted in the optic nerve bundle, or in the posterior columns of the cord, or in the hemisphere, although the events of the three cases differ most widely. In the second class will be placed such cases as hemiplegia from cerebral hæmorrhage, loss of speech from embolism, and convulsions from the secondary changes which cerebral tumours give rise to. The *idea* would be the same whether the blood were effused in the nervous tissue forming part of the pores of the cerebellum, or of the retina, although the *events* would differ extremely.

Dr. Hughlings Jackson next, in illustration of what he had just said, related some particulars from the medical history of one family. The eldest girl—the patients were all daughters—had what, for shortness, he would call idiopathic epilepsy—almost, he added, a metaphysical expression. The next, atrophy of the optic nerves, and occasional petit-mal. The third, unilateral chorea. The mother of these children had rheumatic fever when her youngest daughter had chorea, and she died (through her lungs) of disease of the heart a year later. She, herself, had had chorea when a child, and a second time in one of her pregnancies. The child, the subject of chorea, had a mitral murmur which persisted when she was rid of all irregular movements, and her elder brother not long after suffered from an attack of acute rheumatism. Here seems an inheritance, not of a tendency to nervous diseases, but of those ill-defined tendencies to particular morbid processes which are called arthritic. He (Dr. Jackson) holds strongly that the chorea in mother and daughter cannot safely be admitted as evidence of the transmission, except in a very roundabout way, of a tendency to nervous disease. It is, he thinks, rather a sign that there was transmitted a tendency to disease of tissues of much lower function than the nervous, which tissues being affected in the valves of the heart, led to cerebral disorder through the quasi accident of embolism. This view as to one manner of alteration of nerve-tissue in chorea is, he admits, so far an unverified speculation; but, then, so is nearly the whole of our knowledge, so-called, of the state or states of nerve-tissue, which permits either irregular movements or spasm of muscles. And our knowledge on many diseases of the nervous system is, he thinks, likely to remain speculative so long as we spend most of our thoughts in speculating about the immediate causes of epilepsy, of chorea, &c., when those speculations do not lead to a more active and orderly search for facts to establish the *laws* of the simpler phenomena of these diseases or symptoms. For instance, as regards the outward signs of disordered function, we may study from individual cases in what way muscles and muscular groups, in one physiological region—*e. g.*, of the limbs—can suffer from health, through irregular movements and spasm of muscles, to paralysis, and thus learn the laws of muscular life in health and disease. But to return: There are other possibilities of disease in this family. The second daughter—the one amaurotic—had malformation of the teeth; that particular sort of deformity which Mr. Hutchinson has found to be due to inherited taint. Thus it becomes a question whether this girl and her elder sister had not inherited the syphilitic cachexia which had given rise to, or rather permitted, disorderly growth in one of the commonest tissues. And the fact that their nervous organs had been somewhere damaged by the results of this disorderly life in a low vulgar tissue, was not the most essential one, patholo-

gically considered, as connective tissue in other organs—*e. g.*, in the liver—frequently suffers from syphilis when that of the brain is so diseased. Here it seems worth passing attention that the artificial separation of function and life seems partly warranted by what we know of the resemblances and differences of nerve tissue and connective tissue. The one may be called a tissue of high function—it is of elaborate structure—but of low life. The other—the connective tissue—plays a very subordinate part in nervous tissue, the real celebrant in the functions of nervous organs, but in disease it not unfrequently heedlessly indulges its speciality for mere vegetable growth, although the new products die almost as fast as the mass increase in size. Thus nerve tissue frequently suffers from no fault of its own.

These distinctions obviously bear on the way in which we should try to arrive at a rational system of therapeutics. It is, he (Dr. Jackson) fully admits, most satisfactory at present to adopt a sound empirical system of treating many nervous diseases. But to pretend to a *rational* treatment of diseases of which the tissue changes are altogether unknown—for instance, to talk of a *rational* treatment of so-called idiopathic epilepsy, is not practical. Much of our so-called practical knowledge is really an acceptance of metaphysical explanations and a treatment of entities. Progress in the therapeutics of nervous diseases will, he believes, come from such workers as those who find out how and where tissue is changed from health, and not from those who try one mineral or vegetable after another to find out what thing best decreases the “increased excitability of the medulla oblongata.” The attempt to divorce the study of therapeutics from a real positive study of states of disease is, however, he (Dr. Jackson) thinks almost quite out of fashion. Those who have not fine enough perceptions to observe slight differences in pathology will not be credited to possess perceptions fine enough to observe the slight changes in the course of disease which many of our remedies can produce.

Dr. Jackson next spoke of injuries to the head. He has not unfrequently been consulted for certain epileptic seizures which have followed some time after blows on the head—seizures physiologically related to the part injured—but he has never been consulted for insanity caused in this way. This fact is, he holds, not one of any value all towards showing that insanity may not even often follow gross damage to the brain. Whilst a general physician is likely to be consulted by epileptics, he is not likely to be consulted for insanity from any cause whatever.

He (Dr. Hughlings Jackson) then remarked generally of epilepsy. He thinks the term epilepsy is unfortunately very indefinite one, and that it is especially hurtful when it is used very decisively for a definition of the most commonly occurring chronic convulsions. He thinks it most likely that the unknown condition of the nervous system in epilepsy may produce almost any set or degree of nervous symptoms, according to the part of the nervous system affected, as the motor tract, or the outlying parts of the hemisphere. He alluded to the case of a patient who used to pass suddenly into a state somewhat like that of a somnambulist; next, to that of a woman who had had some maniacal attacks in her sleep, and who was, by her own wish, strapped down every night; next, to transitory following convulsive attacks. Yet all these patients seemed quiet and sensible people. He supposes the epileptic condition, whatever it is, temporary and permanent in these cases, during the paroxysm affecting some critical parts, also unknown, of the hemispheres.

In every case there are to be studied—(1) changes of tissue, (2) damage of organs, and (3) disorder of function. In coarse diseases of the nervous system we sometimes make out all the three with comparative completeness, as when (3) hemiplegia occurs from (1) softening of nerve tissue of the (2) corpus striatum. In many cases of chronic convulsions we can get to know only the first, and it cannot be too much borne in mind that we have in “epilepsy” the two others to find. We should

seek them in an orderly manner. In some convulsive seizures—*e.g.*, those in which the spasm of muscle is unilateral—we may sometimes get to know something of each of the three. In insanity, he (Dr. Jackson) imagines, the same positive plan of study ought to be followed as soon as ever it becomes possible. At present it seems scarcely likely that, in most cases at least, we can do more than study insanity as a disorder of what we know of healthy function of brain—*i.e.*, of mind—and not much as to its dependence on particular changes in nerve tissue which allow that disorder, and not even as to the seat of those changes—the part or organ affected. It is perhaps a truism to say that disease is a departure from health, but he (Dr. Jackson) remarked that even in the study of the simpler nervous affections—such diseases as chorea, epilepsy, &c.—the attempt seems to be, not to determine how far and in what way the symptoms show a *departure* from healthy states of tissues, organs, and functions, but how nearly cases *approach* our conventional notions of *genuine* epilepsy, &c. He did not know if this plan were the sole method of any medical psychologists. He might, he thought, easily venture to say that it was not the method the author had followed. In spite of a temporary convenience, it will not, he fancied, be very profitable to try to determine how cases of disorder of mind approach or recede from arbitrary standards of mental disease. Yet, very possibly, for a long while this unprofitable plan must be followed in great part. But it need not be followed in some nervous diseases which present certain symptoms, which symptoms reveal links betwixt motion and thought. So, while psychologists are studying cases of insanity as departures from mental health—*i.e.*, as disorders of function of brain—they may also, he imagines, do good work in cases of hemiplegia, apoplexy, uræmia, chorea, &c., towards helping the putting in order of those slighter symptoms which may be called either defects of rudimentary mental or of highly-developed physical processes. This is, he thinks, especially applicable to defects following damage to the hemisphere near the corpus striatum. In such cases we can frequently trace a gradation from simple disorders of motion to symptoms which are called mental; or, to put this in convenient technical terms, from psychico-physical—*i.e.*, gross movements to physico-psychical, as disorder of the educated movements of language, or perhaps we may say of motor-impulses of thought. In chorea there are often ordinary mental defects, from slight nervousness and ill-temper up to—what, it is true, is very rare—actual imbecility. And, in a few cases of chorea, hints seem, as in other cases already mentioned, to be given us of a method of studying movement and thought as one series of motions ascending from gross movements to the very borders at least of the motor impulses of thought. Such cases, he believes, when fairly and widely studied by both general and special practitioners with the other cases already mentioned, will help us to establish valuable laws of physical and psychical processes. He thinks that many little symptoms in chorea may have that sort of value to the psychologist which little words have in giving meaning to technical terms in a sentence, to round off his special knowledge. The common movements of chorea—*e.g.*, those of the arm, are not heedless jerks of muscles, but a profusion of real motions—not a random striking of notes, but a rapid series of chords—and hence the term *psychico-physical* may well be applied to these symptoms of muscular disorder, although in a wide sense all purposive movements are both physical and psychical phenomena. Dr. Jackson next said that by working more in harmony, more would be known about such a disease as puerperal mania. The wide study of the puerperal group of nervous affections would require the organized efforts of obstetricians, general practitioners, and alienists. A woman in labour is liable to have—here speaking of some of those symptoms only which continue after the crisis of parturition is well over—epileptiform seizures, hemiplegia, with or without loss of speech, chorea, and mania. Now he (Dr. Jackson) thinks that by working

together, medical men will have not only what they to a great extent have already—*viz.*, a knowledge of many facts about nervous diseases—*i.e.*, disorders of functions following labour, but much knowledge of the particular ways in which the tissues and organs of the nervous system are liable to suffer in the physiologico-pathological process of childbearing. For instance, it may be, as he (Dr. Jackson) thinks is not very unlikely, that these widely different disorders of function are due to but one kind of change in nerve tissue—*viz.*, softening from plugging of more or fewer vessels of varying size and in different parts of the nervous system. The speaker concluded by saying that he feared he had contributed but little of value to the direct questions raised by the author, but he hoped the narration of his (Dr. Jackson's) different experience—indeed, as regards insanity, almost the confession of a no-experience—might be of value, if, in the very slightest degree, it helped to get rid of the too narrow study of disease in artificial divisions.

Mr. BAKER BROWN, junior, thought, with the author of the paper, that self-abuse in women was frequently to be considered rather as a symptom than as a cause of insanity. In lunatic asylums, the practice was very common among the insane. Some cases of insanity had derived benefit from the practice of excision of the clitoris, recommended by Mr. B. Brown; but the operation was chiefly beneficial to persons affected with acute hysterical symptoms. He could scarcely think with the author of the paper that sexual excesses were common among married persons; but thought that it was solely among the unmarried that these led to insanity; and, with regard to religion being a cause of insanity, he thought such cases were chiefly to be met with among partizans of the extreme orders of religious sects, such as Methodists on the one hand, or High Churchmen on the other; whilst he had remarked that persons who adhered to the moderate established system were not so apt to go mad from religious zeal.

Dr. CLEVELAND was not quite certain to what extent the author's statement with regard to the increase of the proportional number of insane persons should be accepted as proved. He was inclined to believe that there were more lunatics, because the population was greater; but not that there were more in proportion. To give the debate a practical turn, he wished to remark that, since intemperance appeared, as was well known, to be such a frequent cause of insanity, it seemed to him that something should be done, like that suggested by Dr. Winslow, towards establishing a sanatorium, where drunkards could be kept until the fit of drunkenness subsided.

Mr. BENSON BAKER said he had had some experience of insanity among the poor, and had found drunkenness a very fruitful cause of it among that class. After this, as a cause of insanity, he thought, came consumption. Among the poorer classes, dipsomaniacs entered hospital and recovered; whilst the rich drunkard was worse off in this respect, because he could not be easily removed out of the opportunity of obtaining drink. He considered that signing of certificates of insanity was too great a responsibility to put on a medical man, and that the present law on this point required alteration.

Dr. CAMPS said that, in Scotland, there existed asylums for dipsomaniacs like those spoken of by Dr. Cleveland, and it would be well to introduce them into England. He did not think that epilepsy should be looked upon as a cause of insanity, but rather as a consequence of the disease. Many cases of insanity which he had observed had been accompanied by other diseases, such as tuberculosis, &c. He did not think that religion could justly be considered a frequent cause of insanity; indeed, in his opinion, true religion rather tended to ward off any tendency to insanity.

Dr. BROADBENT said he had rarely listened to a more instructive paper and debate. The first idea developed by the author was, that insanity was a form of degeneracy, traceable either to moral depravity, or physical privation,

bad hygiene, &c. He was struck with the prominence given to moral causes. Another idea of Dr. Jackson's was important—viz., that it was rather tendencies to degeneration of tissues that were inherited, than diseased organs. Much good might result from unanimity of working between those occupying themselves with diseases of the brain and those employed in the kindred subject of the treatment of the insane.

Foreign Medical Literature.

A CASE OF

LIGATURE OF THE COMMON CAROTID ARTERY FOR A PULSATING TUMOUR IN THE ORBIT,

Read before the Royal Medical Society of Copenhagen,

By C. WITTHUSEN.

Translated from the *Ugeskrift for Læger*, 16th June, 1866.

By WM. DANIEL MOORE, M.D. Dub. et Cantab., M.R.I.A.,

HONORARY MEMBER OF THE SOCIETY;
EXAMINER IN MATERIA MEDICA AND MEDICAL JURISPRUDENCE
IN THE QUEEN'S UNIVERSITY IN IRELAND.

LIGATURE of the carotid artery is so often performed, and is under ordinary circumstances such a comparatively easy operation, that it is scarcely worth while to note every individual case; nevertheless, I venture to lay before the Society the following history as it is, because, both before and after the operation, the case presented certain difficulties in diagnosis, which it may be interesting to endeavour to clear up:—

Anna Börgesdatter, from Sweden, aged 44, unmarried, is reported to have hitherto always enjoyed good health and to have had a good constitution. Fourteen months before her admission into the Municipal Hospital, which occurred on the 28th June, 1864, she began, without any cause known to her, to experience a weakness of vision in the right eye, which she describes as a mist before the eye, which was particularly dense when she looked downward. The weakness of vision gradually increased, without any other symptoms, during a couple of months; she then began to complain of pain in the bulb, with intolerance of light and flow of tears, with swelling of the eyelids. The pains were tearing and pricking, only occasionally were they slightly throbbing, and appeared to her to proceed from the interior of the eye, whence they radiated into the right temporal region; they were often accompanied with flashes and sparks before the eyes. At the same time the patient observed that the eye was pushed forward with an increase of the weakness of vision, the pains assumed more and more of a throbbing character, nevertheless they were not constant, and might sometimes cease for the whole or half the day. She began also to hear a throbbing and whizzing sound in the ear. In the month of August, 1863, iridectomy was performed on her in the Christiansstad Hospital, after which she remained there for seven weeks. Shortly after, however, all her symptoms became aggravated, especially considerable conjunctivitis, the pains in the temporal region and the whizzing in the ear increased, as did the exophthalmos. Her general health began to suffer, she had dislike to food, was thirsty, felt languid and weak, emaciated considerably, and was wearing away before her admission into the Municipal Hospital, without anything essential being done for her, at least without any beneficial treatment having been employed.

The patient presents an appearance of suffering, and is considerably emaciated. The lids of the right eye are swollen, as is the conjunctiva of the globe; the globe is pushed almost out of the orbit, so that it projects fully an inch more than the left. The upper lid is pushed upwards and cannot be brought spontaneously down over the eye, but it can be brought down passively, and then retains its place for some time; it is of a bluish red colour, and has

transparent varicose vessels. These are directly connected with some very dilated veins in the temporal region, and among the latter winds the temporal artery in a serpentine manner, strongly pulsating, and much dilated. A considerable vascular connection seems also to exist between all these vessels and the tumour in the orbit, which shall presently be described. The conjunctiva of the globe is in its lower part highly chemotic, forming great longitudinal folds; the lower lid is less swollen, and as if quite pushed back by the globe. The conjunctival vessels extend somewhat over the edges of the cornea, and in the inner and lower half of the latter is seen a grayish-white opacity of the parenchyma, while the remainder of the cornea is uniformly dull, but still rather transparent. The iris is immovable, the pupil is slightly dilated, with a considerable artificial coloboma. On account of the opacity ophthalmoscopic investigation yields no result.

In the upper and outer part of the orbit a tumour is perceptible, extending rather over the supra-orbital margin; the edge of the bone is here felt to be uneven and rough, and beyond the outer angle it appears to be absorbed. The tumour is found to be immovable, in its inner parts it is softer, farther outwards it becomes harder, less elastic, and more dough-like; it does not fluctuate; if strong pressure be made on it, the patient feels pain, and a distinct pulsation is observed, isochronous with the pulse at the wrist, and so strong that the finger with which the pressure is made is perceptibly raised. The pulsation is entirely removed, and the swelling becomes evidently diminished on compression of the carotid; its volume is on the contrary increased when the patient is made to bend her head forward, and so to produce greater congestion. With the aid of the stethoscope a distinct intermittent whizz is heard in the tumour. The pains are violent, throbbing, for the most part confined to the temporal region. They are constantly present, as is the noise in the ears, already mentioned. The power of vision is so much weakened that the patient can distinguish objects—fingers for example—only when they are very near the eye.

There is want of appetite, the tongue is clean, the bowels are regular, the pulse is soft and natural.

On examining the heart the dulness is found to be scarcely increased in extent, the cardiac impulse is felt in the normal situation, the sounds are accented, and are propagated over the whole chest, and up into the cervical vessels. The first is prolonged, with a rough accessory sound, which is heard most strongly at the apex, sometimes with a ringing character. The patient has for the last two years occasionally suffered from palpitation, but not from dyspnoea.

During the four days spent in the hospital before the operation was undertaken, the pains in the right side of the head were very violent, especially at night, so much so as to prevent sleep; the chemotic swelling of the conjunctiva increased, as did the opacity of the cornea.

On the 2nd of July, an aneurism in the orbit having been diagnosed, a ligature was applied upon the common carotid, at the point of decussation of the sterno-cleido-mastoid with the omohyoid muscle, in the plane of the middle portion of the thyroid cartilage. The operation, which was performed without chloroform, presented no difficulties; the internal jugular vein was not even seen. The hæmorrhage was extremely inconsiderable, and only a single cutaneous branch of the anterior jugular vein which crossed the seat of the ligature, and was highly dilated, had to be tied and divided. Several venous branches of various sizes, external to the fascia colli profunda, were held aside, and, when the operation was completed, again appeared, covering the seat of the ligature. The wound was united with *serres-fines*.

— When the ligature was closed, the pulsation in the orbit and temporal artery forthwith ceased, the tumour diminished, and the throbbing pains, together with the whizzing in the ears, disappeared.

In the course of the day the patient had some oppressive pain extending over the whole head — *Epihema*

glaciale. The temperature of both sides of the head was the same, and the sensibility of the skin was unimpaired.

July 3rd. The patient has slept occasionally, but has had slight nausea and difficulty in swallowing, for which an enema was administered with good effect, and Seltzer water. The nausea has now ceased, and she feels perfectly well in that respect. There is only slight pain around the wound, no redness. The tied end of the carotid pulsates strongly. The chemotic swelling of the conjunctiva is considerably diminished, and the cornea is clearer.

July 4th. The patient's condition has, on the whole, improved, as the pains in the head are lessened, and are felt only as a weight in the whole head. The feeling of pulsation has ceased. The tumour in the orbit has become harder, no pulsation whatever is to be felt. The eye has somewhat retracted, so that the upper lid can be spontaneously brought to cover it. She has no longer the troublesome feeling of dryness in the eye. In the temporal artery there is a scarcely perceptible perfectly thread-like pulsation. The pulsation in the central part of the carotid is to-day not to be felt, but a slight shock is communicated from the *arteria innominata*.

On the 5th July the bandages were taken away. The wound was united, only in its middle was there a slight discharge of pus with slight swelling and redness about it.

July 6th. The patient feels no pain in the head, but only some confusion when she awakes. The cornea is evidently clearer and she can distinguish objects better. The eye is a little less prominent, and the pulsation is not at all perceptible.

July 20th, the eighteenth day after the operation, the ligature came away; the wound is almost healed.

July 31st. The eye has retracted so much that the patient can quite close the lids. The chemosis has disappeared; and the cornea is rather clearer; she got up.

In the first days of August the patient began to suffer from home-sickness, tendency to diarrhoea supervening. She complained also of pain and mist before the left eye, in which, however, nothing abnormal was discoverable, either on internal or external examination.

On the 11th August she decidedly requested to be dismissed, in order to set out for Sweden. The eye was then still rather prominent, without chemosis, the cornea, as has been mentioned above, was rather clearer than before the operation. The power of vision was not much improved.

A year elapsed before I succeeded in obtaining any information as to the patient's further fate, which I then owed to the especial kindness of Dr. Holmer in Christianstad, who himself examined her in the beginning of August, 1865. The eye was then still very prominent, even "hanging down on the cheek," the tumour was, according to her report, of the same size as when she came into hospital; it had extended towards the temple by a length of one-and-a-half inches, and by an inch in breadth, and externally to it the pulsating temporal artery could be distinctly felt. No pulsation was perceptible in the tumour itself. An exploring trocar was introduced deeply into it, and gave exit to a stream of bright red blood. The patient was much tormented with rheumatic pains in the body, and was, moreover, very weak, in consequence of long confinement to bed, caused by fracture of the neck of the thigh-bone.

I was unable to procure any subsequent information about her.

In fixing the diagnosis of this tumour, it is not easy to decide of what nature it properly was. Vascular tumours in the orbit may be formed, either by a dilatation of the existing vessels, telangiectases, and to these a great proportion of the pulsating tumours cured by different surgeons by tying the carotid artery were formerly referred; but the more recent writers, and especially Demarquay, who has produced an exhaustive work on "Aneurisms in the Orbit," are of opinion, that in these cases a false diagnosis has been made, and that the operators had to do with actual aneurisms. They base this opinion upon the facts that such tumours are in general congenital and in-

volve the outer skin, and that only in extremely exceptional instances are they the seat of pulsation and bellows murmur, and that they are not cured by tying the nearest principal trunks. The other kind of vascular tumours, the cavernous tumours, consist, according to Förster, of meshes of connective tissue and smooth muscular fibre, which are lined internally with epithelium, contain blood, and are only in their periphery, as it were, seated on the pre-existing vessels. Gräfe has in the seventh volume of the *Archiv für Augenheilkunde* described such a tumour, which he extirpated after having enucleated the eye. The disease had begun with disturbance of vision, which gradually increased to almost total blindness; by degrees the eye became more and more protruded from the orbit, until at last it turned the eyelids completely back; the tumour was elastic, of varying consistence, not fluctuating, and gave rise to pains, partly in the orbit itself, partly in the temporal region, and the whole of the same side of the head; its volume and tension increased when the patient bent his head strongly forward.

Besides the vascular tumours, proper true aneurisms are found in the orbit, but these are very rare, as only one authentic example is said to exist, which was observed by Guthrie, and another accidentally met with in a dead body by Carron du Villars. They both had their seat on the ophthalmic artery; in Guthrie's case on both sides. On the other hand, many examples of diffuse or false aneurisms, some primary, some consecutive, are met with. Of the diffuse primary, proceeding from a traumatic cause, some have been cured by tying the carotid, some by the injection of a coagulating fluid. The same favourable result has been obtained also in several cases of diffuse consecutive aneurisms, which have always arisen suddenly in an effort or during pregnancy, and which we must attribute either to an original true aneurism or to an atheromatous degeneration of the walls of the ophthalmic artery.

Finally, we have many interesting examples of pulsating tumours in the orbit, which had no connexion whatever with either vascular tumours or aneurisms, but were due to disease in the orbital veins, or to a cancerous swelling. Wecker has in his *Etudes ophthalmologiques* reported a case where all the symptoms of an aneurism existed in a well marked degree, but where dissection exhibited a considerable morbid dilatation and attenuation of the orbital veins, which had in several places burst and had given rise to considerable extravasations of blood, where there had consequently been a pulsation communicated from the carotid and ophthalmic artery.

Another case is reported by Hulke, who saw it with Bowman. It resembled aneurism so strongly that Bowman applied a ligature to the carotid; but when the patient died of repeated hæmorrhage, dilatation of the ophthalmic vein was found on dissection, the vessel running a very tortuous course, and communicating with the sinus cavernosus, which was also dilated.

That cancerous tumours also may be the seat of considerable pulsation has often been shown, and a good example of this fact is supplied by an observation of Lenoir, communicated by Wecker, where on the supposition that the case was one of aneurism, the carotid was tied, though on the patient's death, which occurred nine months later, a considerable encephaloid tumour was found, together with other similar tumours in other organs.

If we now revert to the case above reported, I had, before I undertook the operation, no doubt that I had to do with a true orbital aneurism. The stronger pulsation in connection with the feeling of expansion, the cessation of this and diminution of the swelling on compression of the carotid, were the principal phenomena which involuntarily led our thoughts in this direction; the gradual development of the disease, the absence of any traumatic cause, or of a definite moment for its commencement, limited the exact diagnosis to a true aneurism, and finally, the signs, though weak, derived from the heart, gave a certain probability to a possible affection of the arterial system as a causal element of a morbid change in the

walls of the ophthalmic artery. It was on this supposition that I determined on and performed the operation of applying the ligature, and it appeared in the short time that the patient remained in hospital as if there really were grounds to expect a favourable result. The pulsation ceased, the swelling and pains diminished, and the patient, on the whole, enjoyed comparatively good health, when an attack of home-sickness rendered it necessary to forego the opportunity of further observation. But I cannot deny that the information received a twelvemonth later must considerably shake our faith in the correctness of the diagnosis. The tumour had increased without a return of the pulsation, the eye was more protruded, the patient's general state was worse, rheumatic pains had set in; all this would point to a dyscratic affection, a suspicion which was not diminished by the fact that blood issued copiously through the explorative puncture, as it is expressly remarked that this was performed with a sharp trocar, and that the blood was drawn up with a syringe.

June 6th. As a postscript to the foregoing communication I have to add, that, according to a report recently received, the patient died in the month of May, 1866, the tumour having constantly and uniformly increased. She had latterly had violent pains in it, and had been so lethargic that she could not give any accurate account of her state.

SUMMARY OF SCIENCE.

(Specially Edited and Compiled for the Medical Press and Circular.)

By CHARLES R. C. TICHBORNE, F.C.S.L., F.R.G.S.I., &c.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

ON THE SOURCE OF MUSCULAR POWER.

DR. FRANKLAND has been devoting his attention to the above important subject, and has given the results of his experiments in the form of a lecture delivered at the Royal Institution. The lecture, as given by him, would fill at least one whole number of THE MEDICAL PRESS AND CIRCULAR; therefore the reader will comprehend that the following summary is but a brief description of this discourse. The author commenced by describing the source of muscular power—that from food alone comes all the different kinds of physical force which an animal is capable of manifesting. A few years ago this force, says Dr. Frankland, would have been called vital force, but now no one would venture to return such a reply. [We must, however, make a distinction between vitality, the connection of the mind and the animal, and the misnomer vital force, which confusion emanated from an indistinct idea of the constructive power of the mind.—ED. S.]

The two chief forms of force are heat and muscular motion, or mechanical work, and these have been almost universally traced to two distinct sources—the heat to the oxidation of the food, and the mechanical work to the oxidation of the muscles. Liebig says that all the living parts of the body are derived from the albumen of the blood. The sulphurized and nitrogenous constituents of the food determine the continuation of the manifestation of force, the non-nitrogenous serve to produce heat. The former are the builders of organs and organized structures, and the producers of force; the latter support the respiratory process.

This doctrine—viz., that the actual muscular force is produced by the disintegration and destruction of itself, has been within the last few years the accepted theory, and Dr. Frankland quotes from Rank, Playfair, Odling, in which they take this view, but Frankland, Mayer, and others challenge this view. Mayer writes as follows upon the subject:—"A muscle is only an apparatus by means of which the transformation of force is effected, but it is not the material by the chemical change of which mechanical work is produced." He says, "The fire-place in which this combustion goes on is the interior of the blood vessels, the

blood is the oil in the flame of life, the muscle produces mechanical work at the cost of the chemical difference consumed in its capillaries. Every act of motion in an animal is attended by the consumption of oxygen, and the production of carbonic acid and water; every muscle to which atmospheric oxygen does not gain access ceases to perform its functions."

These ideas did not, however, emanate from Mayer. Two hundred years ago a Bath physician, John Mayow, said that the conveyance of combustible substances to the muscle was by the blood. He concluded that the chief combustible substance so used was fat. These views have, within the last two years, been resuscitated, but experimental evidence was wanting—viz., the amount of actual energy generated by the oxidation of a given weight of muscle in the human body; and the question which Dr. Frankland seeks to solve, in connection with the above, is—What is the quantity of heat that is generated when muscle is burnt, to the products in which its constituent elements leave the human body through the lungs and kidneys?

It is necessary first to estimate the amount of actual energy generated by the muscle in oxygen, and then to deduct from the number thus obtained the amount of energy still remaining in the products of oxidation which leave the body. Of these products, urea, uric, and hippuric acids are the only ones in appreciable quantity [? ED. S.] and of these which still retain potential energy on leaving the body, the two latter are excreted in such small quantities that they may be considered as urea, without introducing any material error into the results.

In the first place, it is necessary to agree upon some unit for the measurement of mechanical force. The unit adopted is that represented by the lifting of a kilogram weight (about two pounds) to the height of one metre (about one yard). The force employed in the lifting of this weight 425 times would, if converted into heat, raise the temperature of an equal weight of water 1° C.; therefore, it follows that the falling of 425 kilograms through one metre will raise the temperature one degree; or the collision of one kilogram with the earth, falling from a height of 425 metres, would produce an amount of heat that would raise the temperature of a kilogram of water 1° C. This standard of force is termed a *metre-kilogram*.

425 metre-kilograms = the amount of heat necessary to raise one kilogram of water one degree.*

The determinations were made in Lewis Thompson's calorimeter, an instrument by which the amount of heat generated during the combustion of a given weight of any combustible substance can be very fairly estimated.

The actual energy developed by one gram of substance, when burnt in oxygen, is expressed by the *metre-kilogram*, which, it will be remembered, is the arbitrary standard of force.

	Metre-kilograms of force
Beef muscle washed with ether to purify it from fat, and dried at 100° C	2161
Albumen	2117
Beef Fat	3841
Hippuric Acid	2280
Uric Acid	1108
Urea	934

} Mean of 4 experiments.

Now, in the body, the whole of the nitrogen passes out of the body as urea. It is not entirely burnt, as in the experiment of the calorimeter. Dry muscle and pure albumen yield exactly one-third their weight of urea. Under these circumstances, these facts, taken collectively, have enabled Dr. Frankland to deduce the amount of actual energy developed by muscle and albumen when consumed in the human body.

	Metre-kilograms of force
One gram of muscle, as burnt in the human body	= 1848
„ albumen „	= 1803

Thus is the first of the three data found—viz., the amount of force or actual energy generated by the oxidation of a given amount of muscle in the body; and we now proceed

* It may be as well to explain that in the metre system, which has been very generally adopted in Great Britain, the French word *gramme* has been converted into gram, and therefore all the derivations follow the same rule.

to the second and third data. These were determined by MM. Fick and Wislicenus, who made an ascent of the Faulhorn, a mountain in Switzerland, for this purpose. The account of their journey, which is as interesting as a romance, is given in the *Phil. Magazine*, vol. xxxi., p. 496, from which Dr. Frankland quotes largely; but we can only give the heads of their observations here.

The first question they propounded for themselves was how much work was really performed by their muscles. The height of the summit of the Faulhorn, from the Lake of Brienz, multiplied by the weight of their bodies, Fick performed 129·096, and Wislicenus 148·658 metre-kilograms of muscular work; and to be added to this were the force consumed in the action of respiration and the heart's action, which, having been estimated, brought the figures up as follows:—Fick's work, 159·637; and Wislicenus' 184·287 metre-kilograms, executed in five hours and a quarter.

The third item wanted was the amount of muscle oxidized in the body during the performance of the works:—

	Fick.	Wislicenus.
Nitrogen secreted in urine per hour before ascent	0·63	0·61 grams.
Weight of muscle consumed in the body and corresponding to this nitrogen	4·19	4·05 "
Nitrogen secreted per hour during ascent	0·41	0·39 "
= Muscle	2·70	2·56 "
Nitrogen secreted per hour for six hours after ascent	0·40	0·40 "
= Muscle	2·63	2·63 "
Nitrogen secreted per hour during the following night	·45	·51 "
= Muscle	3·06	3·39 "
The total amount of nitrogen secreted during the ascent, and for six hours afterwards, was	5·74	5·55 "

And the weight of dry muscle, corresponding to the nitrogen secreted during the ascent and for six hours afterwards, was

37·17 37·00 "

There are sources of error, for which ample allowance was made by Dr. Frankland.

On comparing the amount of measured and calculated work performed by each of the experimenters during the ascent, with the actual energy capable of being developed by the maximum amount of muscle that could have been consumed in their bodies, it is evident that the muscular power expended could not be exclusively derived from the oxidation, either of the muscles or other nitrogenous constituents of the bodies, as the maximum power capable of being derived from this source, even under very favourable assumption, is, in both cases, less than one-half of the work performed. Dr. Frankland tabulates the results in the following manner:—

	Fick.	Wislicenus.
Weight of dry muscle consumed	37·17	37·00 grams
Actual energy capable of being produced by the consumption of 37·17 and 37·00 grams of muscle in the body	68·690	68·376 metre-kilograms.
Measured work performed in the ascent (external work)	129·096	148·656 "
Calculated circulatory and respiratory work performed during the ascent (internal work)	30·541	35·631 "
Total ascertainable work performed	159·637	184·287 "

Thus falls to the ground another beautiful theory which had been viewed as an axiom for some years past.

ON THE REARING OF TÆNIA ECHINOCOCCUS IN THE DOG FROM HYDATIDS.

A paper was read before the Royal Society, which possesses some interest in connection with the subject of alternation of generation in the entozoa. Mr. E. Nettle-ship says that, "although Dr. Cobbold has succeeded in rearing a variety of tapeworms from their respective larvae,

the tænia echinococcus has not hitherto been reared in this country." The author obtained the liver and lungs of a sheep containing numerous echinococcus hydatids. In some the outer cyst was partially calcified, but all the hydatids contained clear fluid.

A young dog was fed with the hydatids, the hydatids being first punctured, and the collapsed cyst administered; he was made to drink the fluid of the cyst, in which some echinocci were floating. The dog remained perfectly healthy, became very much fatter, and was killed forty-seven days after the first feeding. He received no raw food. On examining the intestines there were no tænia in the first ten inches below the pylorus; at that distance a single tænia echinococcus appeared moving actively. For the next two or three inches there was none, but at about fourteen inches below the pylorus more appeared, and immediately after this they became so numerous as to present almost the appearance of distended lacteals. There were also four specimens of *T. Marginata* and *T. Cucumerina*. The author also makes some observations upon the anatomy of the sexual organs of the mature worm.

ON THE ALTERATION OF ORGANIC STRUCTURE BY CONGELATION.

In a paper on the congelation of animals by Dr. Davy, in which the author arrives at the almost self-evident conclusion that perfect congelation is antagonistic to life, he refers to the alteration of structure from the same cause. Muscle, according to Dr. Davy, after having been frozen, showed a well-marked difference under the microscope. When thawed the striated structure was no longer visible, and after a few hours—viz., on the following morning—whilst the unfrozen muscles had undergone no perceptible alteration, those which had been frozen had become of increased tenderness, yielding to a slight rending force, and breaking short, as if the coherence of the particles forming the fasciculi was greatly diminished.

PYROPHOSPHATE OF SODA AND IRON.

A solution of 6 parts of pyrophosphate of soda, in 120 parts of water, added to 13 parts of a solution of perchloride of iron (at 1·44 density) gives a precipitate, soluble in 4 parts of pyrophosphate of soda diluted with 78 parts water. This solution, evaporated at 70°, gives, on the addition of alcohol, a gelatinous mass. Dried in the air, this precipitate forms hard scales, yellow and transparent. M. Milch formulates this compound as follows:—

The solution of this compound does not give the usual reaction of the iron salts. The sulphocyanide of potassium gives a white gelatinous precipitate; the yellow and red ferrocyanides no precipitate; acids precipitate pyrophosphate of iron. Ammonia gives a red solution, which yields a very soluble salt.—"Bulletin de la Société Chimique de Paris, Septembre, and Journal für Praktische Chemie."

UPON SOME OF THE SUGARS.

M. Fudakowski says that sugar of milk is a mixture of two distinct glucoses. After boiling with diluted sulphuric acid for an hour, neutralizing with chalk and filtering, and then evaporating to a syrupy consistence, the addition of alcohol determines the formation of crystals, right prisms. The mother liquors left to themselves for some weeks give hexagonal tables as described by M. Pasteur. The sugar, crystallized in hexagonal tables, is more soluble in alcohol than the prismatic sugar. Its taste is sweeter, and it ferments more easily. The rotary powers of these two sugars are different. It, therefore, appears that the sugar of milk, like the cane sugar, separates, after ebullition with acids, into two distinct kinds.

M. Dehn (*Zeitschrift für Chemie*), gives an account of a sugar formed by boiling a glucoside (hesperidine) with diluted acids. Hesperidine is left in the residues after distilling the essence of neroli from the flowers of citrus decumana. Two or three products are described under the name of hesperidine—vide "Watts' Dictionary of Chemistry."

The sugar of hesperidine is very soluble in cold water, and in all proportions in boiling water. The syrup, left to spontaneous evaporation, takes after a little time a radiant crystalline mass. It is very soluble in alcohol.

It does not reduce Fehling's solution (sulphate of copper,

tartarite of potash, and soda). This sugar is, from its composition, an isomere of mannite. Its solution is able to turn the plane of polarisation to the right.

ON THE NITRATES OF IRON.

M. Orday ("Bulletin de Société Chimique de Paris") gives the following as the composition of the nitrates of iron:—The ferric nitrate is deposited in cubic crystals, when the salt is dissolved in hot nitric acid, having the composition " $\text{NO}_3, 3\text{HO}$." It has twelve atoms of water of crystallization " $\text{Fe}_2\text{O}_3; 3\text{NO}_3, 12\text{HO}$;" if a weaker acid is used for dissolving it, the salt is a mixture, and contains more water of crystallization.

The ferrous nitrate—" $\text{FeO}; \text{NO}_3, 6\text{HO}$ "—is obtained by dissolving, at the ordinary temperature, sulphate of iron in weak nitric acid (1 120), by a considerable application of a freezing mixture the salt is crystallized out, and may be preserved without alteration as long as it is kept moist, but is decomposed into a basic salt on drying.

EFFECT OF HEAT RAYS UPON THE EYES—MODIFICATION IN TELESCOPES, &c.

Our contemporary, "Cosmos" (tom. 4, p. 275), describes a modification which might be adopted in telescopes, and even microscopes, with advantage—the calorific or heat rays being extremely dangerous when viewing such bodies as the sun. M. Foucault proposes to take advantage of certain properties possessed by certain metals of arresting the calorific rays, and of letting the luminous rays pass. Silver deposited by a chemical process possesses this property in a high degree. The objective of the telescope is covered with a layer of this metal. The editor of "Cosmos" says that you obtain, by the use of such an instrument, an image perfectly clear, agreeable to the eye, and one which produces no fatigue. The image is exactly similar to what you would obtain by the use of a violet glass.

Reviews.

THE BRITISH AND FOREIGN MEDICO-CHIRURGICAL REVIEW. October, 1866.

THE present number contains ten analytical reviews, twenty-four notices of books, under the heading "Bibliographical Record," three original communications, and other interesting matter.

Of the reviews perhaps the best and most interesting are those respectively entitled, "Recent Danish Works on Helminthology;" and "On Hospitals and their construction."

The original communications, which are all worth reading (particularly the first mentioned, which is very learned), are—"Essay on the Medicine of the Greeks," by T. Clifford Allbutt, B.A., M.B. Cantab.; "On the Reduction of the Subcoracoid Dislocation of the Humerus by Manipulation," by Alexander Gordon, M.D., &c.; and "On the Influence of Age in Hereditary Disease," by William Sedgwick. Altogether this number of the "British and Foreign" is a good one, and quite up to its usual reputation.

THE DUBLIN QUARTERLY JOURNAL OF MEDICAL SCIENCE. November, 1866.

THIS number is particularly rich in illustrations. Mr. Butcher begins it with a paper on amputation of the hip joint, accompanied, as is his custom, by an elaborate illustrative engraving. That he is not to be allowed to monopolise this kind of thing is obvious, from the fact that Mr. Maurice Collis follows hard on him with Part I. of his "Contributions to Operative Surgery," the present paper being confined to "Operations about the Face." These operations are stated to be "illustrated;" and verily they are illustrated to an extent that beats Mr. Butcher hollow, for this number at least. There are no less than fourteen illustrations in a paper extending over just twenty-one pages, and we are confident that it will

be impossible for any one to delineate uglier faces than those here transmitted to posterity for the information of the profession. Mr. Wilson contributes a paper, entitled, "Ophthalmoscopic Notes." Dr. de Ricci returns to the charge, "On the Use of Sulphite of Magnesia in the Treatment of Zymotic Diseases." Dr. Bevan has a paper, entitled, "Reports on Scalds of the Larynx." Dr. Joynt gives a "Case of Protracted Utero-gestation, with Remarks." And Dr. Babington of Londonderry, concludes the original communications with an essay on "Flax-Mills, their Machinery, Accidents occurring therein, with Suggestions for their Prevention." We have here many able reviews; and we have read with pleasure the good value given this month by our able contemporary.

EDINBURGH MEDICAL JOURNAL. November, 1866.

In this number Mr. Syme gives a paper "On Elephantiasis of the Scrotum." Dr. Braidwood concludes his report of Professor Spence's "Clinical Cases;" Dr. Henry Veale gives a very interesting essay on the disease called in Germany "Rötheln," (the Rosalia Idiopathica of Dr. Richardson, and the Rubeola Notha of Dr. Babington). Mr. Stevenson Smith contributes a paper "On the Modern Treatment of Pneumonia in Young Children, with some Observations on the Initial Auscultatory Sign of the Disease." Professor Fayrer of Calcutta, furnishes a good paper, entitled, "Aphasia and Death resulting from Softening in Left Anterior Cerebral Lobe and Cerebellum, due to Atheromatous Degeneration and Embolism of the Cerebral Arteries." And Professor Struthers of Aberdeen, concludes his valuable "Historical Sketch of the Edinburgh Anatomical School."

London Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 21, 1866.

THE CASE OF ABSOLON V. STATHAM.

In this case, which has just been tried in the Bail Court in London, the defendant was charged with assaulting the plaintiff, a female, and administering to her chloroform, and extracting six of her teeth. It was also alleged that she was so severely injured by this proceeding, which occurred in August, 1864, that she had been since incapacitated from obtaining her living, which was that of a dressmaker, and she therefore claimed damages for the injury and loss she had sustained.

Those who have the slightest experience in the transactions of our law courts will perceive at a glance the kind of action to which the present belongs, and perhaps it is hardly necessary to state that the defendant is a gentleman of the highest respectability and skill in his calling. Although not strictly speaking a member of the Medical Profession, he is a Licentiate in Dental Surgery of the English College of Surgeons, his vocation being that of a Surgeon-Dentist, and in that capacity he is attached, as one of the honorary Medical Officers, to the Great Northern Hospital, of which his brother, as is well known, was the founder. He is, moreover, known

among a wide circle of professional and private friends as a gentleman of the utmost kindness and liberality of disposition, not only freely giving his professional advice and assistance to the poor and afflicted, to which class the plaintiff in the action belonged, but also relieving their necessities, when occasion seems to require it, from his private purse. Those who read the particulars of the action will perceive with what diabolical perversion of ingenuity even this amiable trait in his disposition has been used as a handle against him.

Those who know this gentleman's character, and, we may add, all those who believe that respectable Surgeon-Dentists occupy a place somewhat above that of brute beasts in the scale of creation, will at once repudiate the notion that he or any other person in his position could be guilty of assaulting a female, like a common garotter, stifling her with chloroform, violently extracting five of her teeth without her consent, and as soon as she partially recovered her consciousness, seizing her by the throat and forcibly extracting one more; yet all these acts of brutal violence, incredible as they may appear to the rest of the world, seem to be readily believed by the legal mind, which, whatever other qualities may belong to it, is not usually accused of the weakness of excessive credulity. We accordingly find that these monstrous allegations were not only brought forward by the legal advisers of the plaintiff, as if they believed them, but all the plausibility which hired advocates may be induced to assume was employed to convince a judge and jury of their truth.

We may, therefore, without any undue aspersion on the machinery by which the law works out its purposes, regard the above story as a fiction, the only substratum of truth which it possesses being that Mr. STATHAM, after due consultation with his colleagues, removed some carious stumps of teeth from an hospital patient in the usual manner, and that chloroform was administered to mitigate her sufferings, such proceedings being, of course, daily adopted in thousands of cases, both in public and private practice.

But the next point to be noticed is the assertion that the injury said to have been so sustained (and undoubtedly the extraction of a tooth, like any other operation in surgery, is an injury for the time being,) was the cause of the ill-health under which the plaintiff unquestionably suffered, and this being an entirely medical question, it might be supposed that medical evidence would be considered conclusive, more especially if it was unanimous. But although attempts were made to show that the neuralgic attacks experienced by the plaintiff were attributable either to the shock of extracting the teeth, or to the administration of chloroform, not a particle of evidence was produced in favour of such an hypothesis, and in fact all the medical witnesses were decidedly opposed to it. Indeed it was proved that she had suffered from hysteria and neuralgia long before the operation, which was really performed with the hope of

relieving these diseases. The medical witnesses for the plaintiff herself—namely, Mr. GANT and Dr. HYDE SALTER, did not believe that the symptoms were due to the operation, and on the part of the defence, Dr. ANSTIE, Dr. SANSOM, and Dr. RICHARDSON, all of whom may be considered competent or even eminent authorities on the subject, entirely repudiated such a supposition. But notwithstanding this overwhelming testimony on the part of the defendant, the jury were unable to arrive at a unanimous decision, and after being locked up for several hours they were discharged without delivering a verdict.

We come lastly to what may be considered the weak part of the defendant's case, although this admits of a far different interpretation from that which was fastened upon it by the morbid ingenuity of the opposite side. It actually appears that Mr. STATHAM, being moved to compassion by the patient's sufferings, and being naturally, as we have above observed, of a generous and humane disposition, relieved her necessities, as he had done those of many before, from his private purse, and this exercise of kindness was actually tortured into a confession of wrong-doing on his part. We are alluding only to a very common practice when we state that many of our professional brethren, when attending upon the poor and destitute, are in the habit of superadding presents of money, food, and wine, to their medical and surgical ministrations. Heaven forbid that the current of such benevolence should be arrested in its course, even although serpents can be found who, after being warmed and nourished, will turn round and sting their benefactors, and although scoundrels exist who, perhaps judging from their own motives of conduct, will proclaim that such acts of kindness and charity are prompted only by conscious guilt and the fear of legal consequences.

THE SCHOOL OF PHYSIC IN IRELAND.—IV.

In our last number we discussed the clinical part of the School of Physic to some extent, and we now resume this portion of our subject, remarking that much important information concerning the original working of Sir P. Dun's Hospital, and the intentions of the framers of the School of Physic Act, will be found in the first report of the hospital, written by Drs. PERCIVAL and CLEGHORN, and published by the King's Printer in Dublin in 1809 in a 4to volume, entitled, "Report upon Certain Charitable Establishments in the City of Dublin which receive aid from Parliament."

We have already referred to the duties devolving on the Clinical Professors by statute, and also to those imposed on them by the existing hospital system. If we may judge from the ideas of Dr. PERCIVAL, one of the framers of the Act, the labours of the Professors were intended to be supplemented by the assistance of Clinical Clerks; and it is for this reason that the curious reader may, in the volume last quoted, find out what Dr. PERCIVAL intended by the expression "Clinical Lectures,"

of which no precise definition was laid down in the statute. The hospital contains private wards which have always been set apart for the treatment of sick pensionaires or paying patients, who, for a small weekly sum—a guinea or so—receive the best medical attendance and attention which can be had. The benefits of these wards have always been availed of by students resident in Trinity College, and by other respectable persons living in lodgings, or otherwise unfavourably circumstanced for the care and treatment of infectious diseases. We think that here, as in other large hospitals, the Professorial teaching may be largely and usefully supplemented by having for the pupils special kinds of instruction given by extern teachers of junior standing to the Professors. For example, it would be well to have some one conduct a special set of lectures, or rather demonstrations, on the art of bandaging, to be learned by the pupils performing every detail themselves; in fact, a course such as any one may have in Paris from a private teacher for twenty-five francs, with all the beautiful and useful varieties to be found in GOFFRE'S well-known "Bandages, Pansements, et Appareils." The same plan may be followed with other departments in Surgery. Again, in Medicine some junior man may explain, to such as choose to learn from him, the use of the microscope; another may give demonstrations in a special way on testing the urine; a third might teach the use of the endoscope, or the laryngoscope, or the thermometer, or all of them; and even special classes of disease, which require numerous plates and more time than a Clinical Lecturer could fairly give to them in a short course, might be advantageously taught by others. By this means not only would the value of the clinical teaching be enhanced, but special talents would be developed in the pupils. There ought to be, and if we are to judge from Dr. PERCIVAL'S report, there was intended to be, a regular and authentic set of hospital records, as in the larger London hospitals. The great value of such a boon as this may be seen by a glance or two at Dr. TODD'S "Clinical Lectures;" and as there are medical men in London retained expressly for this purpose in the great hospitals, so it should be in Sir P. DUN'S. The mere existence of the office of Medical Secretary or Registrar would create a most useful and accurate class of men in the profession.

The subject of nursing is one which may be fairly introduced here. At various times during the present year we have warmly advocated the institution of nursing sisterhoods among our brethren of other persuasions than the Roman Catholic faith. The system is so far tried and accepted by the Established Church in England, that it needs no defence or advocacy from us; but we think that the Governors of Sir P. DUN'S Hospital should seize the first available opportunity and hand over the nursing of the institution under their charge to a body of this description, if such can be found to undertake it, subject to the wise regulations which are found

so useful at King's College Hospital and elsewhere. The obvious plan would be that on the next vacancy in the matron's office, the lady superintendent of a nursing organization should be appointed to the salaried office of matron, and that she should be paid a fixed sum per annum for having the duties of nursing discharged under her supervision, and with her personal responsibility to the Board. Nothing but religious bigotry of the most miserable kind, or a foolish and obstinate adherence to a bad system, could prevent this being done at the first opportunity, and we are glad to say that there is no prospect of obstructiveness of this kind from the Governors of Sir P. DUN'S; for at the beginning of the present year a proposal after something of the sort here advocated was favourably received, and its adoption was only postponed because, in the opinion of the majority, it was not just then practicable. The majority consisted of the casting vote of the Chairman.

It were well if some space in this hospital were devoted to the treatment of the diseases of females; but we understand that the project will be shortly carried out.

The constitution of the Board of Governors requires some remarks.

Under the School of Physic Act this body is composed of the Visitors (the Lord Chancellor and the three Chief Judges), President, Vice-President, and (four) Censors of the College of Physicians, and the Provost of Trinity College, all for the time being; "and of twelve other persons to be, by said Governors, chosen and elected out of those who may become subscribers to the building or maintenance of said hospital; provided that no physician or surgeon who shall attend patients in the same shall be capable of acting as a Governor of the said hospital" (40 Geo. III., cap. 84, sec. 4). It appears, from the clause just quoted, that no provision is made for the length of time during which an elected Governor may continue to hold his office; and hence some have concluded that, once elected, a Governor may hold on for life. It is remarkable, however, that the Act in no way provides for the succession of elected Governors; while it does provide not only for the succession of Professors, but even for the succession of the eight Commissioners to whom was entrusted the building of the hospital, the duties of these last being temporary, and the Commission itself being dissolved by the act of handing over the hospital to the Governors. It is worthy of note that no provision has been made for the perpetual succession and continuance of the elected portion of the more important and permanent corporation. Hence, according to the strict letter of the Act, the twelve subscribers who were first chosen Governors were lawfully chosen; but these being all long since dead, it may be plausibly maintained that their offices died with them, as the Act did not prescribe that any vacancy should be filled up, much less prescribe the manner of filling such vacancy or vacancies.

In the absence, then, of any direct law, the intentions

of the framers of the Act and the precedents of nearly sixty years may be taken into account, as they assuredly would be in case of appeal to the Visitors.

It appears from the minutes of the Board of Governors that, for some time after the opening of the hospital in 1808, the President and Censors of the College of Physicians were the only acting Governors. Almost the first act of the ex-officio Governors was to draw up, and get confirmed by legal advice, a code of bye-laws, under which, except in so far as they have since been repealed, they still act. One of these bye-laws provided that they would elect Governors for a term of one year only, and that the election should be held annually in March, from those who were subscribers from the January preceding. Accordingly, on the 24th of June, 1808, Dr. PERCIVAL (one of the framers of the Act), Dr. JAMES CLEGHORN (one of its strong supporters), and DAVID COURTNEY, Esq., being then the only subscribers, were chosen Governors for the remainder of the hospital year. On the 6th March, 1809, the first annual election was held, when the three gentlemen just named, with Mr. PARNELL, who had been first elected on the 4th of January in the same year, were re-elected. This precedent has been uniformly followed from thence to the present time. In consequence of some holding the view that the elected Governors of one year could join the ex-officio Governors in choosing their successors, in 1824 a case was submitted to Mr. Attorney-General PLUNKET, afterwards Lord PLUNKET and Lord Chancellor of Ireland, who gave it as his opinion—that any such powers claimed by elected Governors were clearly illegal, and that all elections held in the joint manner above described would be null and void. In 1825 Mr. Attorney-General SAURIN gave a similar opinion on the same question. In 1824 Mr. BLACKBURNE, the present Lord Chancellor of Ireland, gave as his opinion on a case submitted to him—that annual elections of Governors were conformable to the statute; and referring to the bye-laws, which provided that the elections should be held annually, he said :—

1st. The statute does not oblige the official Governors to elect the twelve Governors for any definite period. I therefore see no objection to the regulation or bye-law which, in the case of the election of annual subscribers, limits the duration of their office and authority to a year, and a subscriber so elected cannot contend that he has a right to continue in office after the year for which he has been elected has expired.

2nd. It follows from what I have said that a subscriber, elected under the bye-law or regulation for a year certain, cannot be considered to hold his office for life, or any longer period than the year during which he has been elected to serve as a Governor. I have only to add that it appears to me that the bye-law or regulation limiting the duration of the office of an annual subscriber to the year of his subscription is exactly conformable to the spirit of the Act of Parliament. Indeed I should doubt whether an annual subscriber be eligible for life, for it could not have been intended that any person should remain a Governor after he had discontinued his annual subscription, and thereby ceased to contribute to the funds of the institution."

This opinion did not contemplate the case of a subscriber who makes a life composition for his annual subscriptions. Such a person is, in one sense, a life

subscriber; but as his composition may be returned to him if the Governors so will, he is not *absolutely* a life subscriber. In any case, according to this opinion, the ex-officio Governors can limit or extend the time for which the elected Governors are chosen.

This is a good arrangement, for as the majority of the official Governors can never be regular attendants at the Board, it is of great importance that the efficient elected Governors—who are always re-elected from year to year—should not have their efforts weakened by the association with them of others who may be non-resident, inefficient, or crotchety, and who would only appear for the purpose of carrying "a job."

By the Act the College of Physicians was intended to have a majority among the ex-officio Governors; they were to have had the President, Vice-President, and four Censors; (six) against the four Visitors, and the Provost of T.C.D. In consequence, however, of the ignorance of the framers of the Statute regarding the fact that the Vice-President of the College of Physicians and one of the four Censors must by Charter be the same person, the College loses one Governor. This might be mended by substituting the Registrar or the Treasurer for the Vice-President in an amended Act. The College has frequently lost another vote on the Board by one of the Censors being disqualified, because of his being Physician in Ordinary to the Hospital. This clause ought to be repealed, as no persons are more suitable to be Governors than the medical men attending an hospital; it is commonly the case elsewhere, and even here it is a question whether, for example, the present Vice-President of the College of Physicians, who is also Physician in Ordinary to the Hospital, is not qualified to sit at the Board during the time of his stated *non-attendance* as Physician—that is, during nine months of the year. He has no duties as regards "attending patients in the said hospital" during that portion of the year, and thus it does not appear that he should be disqualified to sit as a Governor while so circumstanced.

We have already advocated the raising of the salaries of the King's Professors to a perfect equality in all respects with the salaries of those on the University foundation, and the repeal of the clause which vacates a Fellowship in the College of Physicians on its holder becoming a Professor. We advocate this on the fair ground that £100 a year Irish for each of three Professors in 1866 is not an equitable representative of £200 a year, which Sir P. DUN left in 1711 to *one* Professor, fearing it was an inadequate endowment for two. Moreover, in all fairness, DUN's intentions as regards endowing Professors should be preferred to any other application of the funds left by him; and therefore the Professorships of Midwifery and of Medical Jurisprudence should be endowed like the others, and a Professorship of Clinical Medicine and one of Clinical Surgery should be founded, to perform the Clinical duties at present assigned to the Professors of Anatomy, Chemistry, Botany, and the University Anatomist. There need be no valid objec-

tion to any of these officers being also Clinical Professor, when declared to be fit for the latter office at the time of election, but ex-officio fitness, as a matter of course, ought to be abolished.

Where are the funds to come from? some one will say. From DUN's estates, we reply.

These estates produce near £4000 a year at present; and according to the calculation of Dr. PERCIVAL, who framed the Statute of 1800, the Professorship of Midwifery ought to have been endowed long ago. The truth is, that so long as an undefined amount of surplus can be applied to support less than 100 patients, so long will it be found insufficient for the purpose. Dr. PERCIVAL's calculation (based on the assumption of the total absence of subscriptions, bequests, and other subsidiary means supporting patients), is, that in the year 1820 the value of the estate would amount to nearly £4000 a year, "which [he and Dr. CLEGHORN say in their report already quoted] will be more than adequate to maintain the number of patients which the hospital is calculated to hold [100]. When the estate can afford it, the surplus fund which will remain after maintaining the hospital, &c., will be applied, agreeably to the Act of Parliament, in maintaining new Professorships and to increase the Library." The fair plan would be to appropriate to clinical purposes a fixed charge per bed (including establishment charges) up to 100 beds; leaving the deficiency, if any, to be met by subscriptions or other contributions, for collecting which there would then be a strong motive, or by reducing the number of beds; the latter is actually done now, there being at present only 80 beds—a number found quite sufficient. £2500 a year would give the large endowment of £25 per annum to each of 100 beds, and would leave a sufficiently large margin for the advancement of the School of Physic, as above suggested. Trinity College has a large interest in the well-being of this hospital—a much larger interest, indeed, than the College of Physicians can now have; and the Board of T.C.D. are subscribers to its funds to a small amount, in recognition of this fact. They ought to raise their subscription to an endowment commensurate in some remote degree with that represented on the Board of Governors by the Visitors and Chief Officers of the College of Physicians, and of course in such case some of the Senior Fellows of T.C.D. ought to be Governors ex-officio.

The School of Physic Act obliges a Fellow of the College of Physicians when elected DUN's Librarian to vacate his Fellowship. This ought to be repealed, for the same reason as in the case of the Professors; and the Library ought to be properly supported and added to out of the estate, as DUN would do were he still alive, and as was done up to the year 1800.

As for any other reforms in the School of Physic, or in the bodies connected with it by law and history, we may merely suggest the institution of lectures on medical ethics, and on medical literature, ancient and modern, the adoption of the tutorial element in some of

the Professorships, the day having passed away when the theory and practice of medicine and of surgery can be taught by Professors' lectures. In the University it would do no harm to infuse new blood among the Medical Examiners by having each year a proportion of non-professorial Examiners, as at Oxford and Cambridge. In Trinity College it were well that the Medical Fellowship, or Fellowships, were made medical in reality and in point of college duties. In the College of Physicians it would serve the cause of Medicine to institute lectureships after the names of eminent members, as at the College in London, and to take something like the move which raised the Licentiates of that body to be Members, making general practitioners eligible to be Licentiates. To do this it is only necessary to restore the class of candidates (from whom alone, as formerly, could Fellows thenceforth be elected) abolished in 1792, and to have that class recognised under the Medical Act; to raise all the present Licentiates to that class; to make eligible to the Licentiateship practitioners who supply and charge for medicines to their own patients, but who do not keep open shop; and to make a Licentiate capable of promotion to the rank of candidate. We now say farewell to the School of Physic, wishing it all success during the coming winter.

CHOLERA.

OUR last week's chronicle of the progress of the epidemic, after an analysis of the official returns for the 44th week of the year, concluded with the daily returns up to Thursday, the 8th instant. It may be natural, therefore, to resume our summary at this point. On Friday, the 9th instant, 8 deaths from cholera and 6 from diarrhoea were registered in London. Of the deaths from cholera, 4 occurred in the East districts, 3 in the South, and 1 in the Central.

The next day, Saturday, the 10th, completing the 45th week, we find the daily deaths from cholera, which had been, during the week, from 5 to 8, rise to 12, and distributed over all the districts except the West. Before passing to the complete weekly return, it may therefore be worth while to give all the particulars of this day:—

SATURDAY, NOVEMBER 10, 1866.

Districts.	Population estimated to middle of 1866.	Total Deaths from Cholera since commencement of the Epidemic.	Total Deaths from Diarrhoea since commencement of the Epidemic.	Deaths from Cholera registered Nov. 10.	Deaths from Diarrhoea registered Nov. 10.
West ...	511,258	182	337	..	1
North ...	686,021	405	505	3	1
Central ...	359,219	324	351	3	..
East ...	607,945	3,892	804	2	1
South ...	873,548	687	542	4	2
All London.	3,037,991	5490	2,549	12	5

Middlesex Hospital—one death from cholera; the patient from Heddon-court, Regent-street. London Fever Hospital—one death from cholera; the patient from 32, Reform-place, St. Luke. King's College Hospital—one death from cholera; the patient from 45, Stanhope-street. St. Bartholomew's Hospital—one death from cholera; the patient from 22, George's-square, Hoxton. London Hospital—one,

death from cholera; the patient from 23, Fashion-street, Spitalfields.

We have now only to sum up the figures for the week. The total mortality was less by 17 deaths than the estimated number, being 1361. There were 67 deaths from cholera and 33 from diarrhœa, making a total of exactly 100 from those two forms of disease. But for the prevalence of the epidemic it is clear that the season would be unusually healthy; since, in spite of these 100 deaths, the total mortality is still 17 under the average. Out of the 67 deaths from cholera 7 occurred in Whitechapel and 13 in Greenwich, Deptford, and Woolwich. The decline of disease is much less rapid than we might have hoped for, as will be seen by the deaths from cholera and diarrhœa during the last 5 weeks, being respectively 254, 199, 144, 101, and 100.

The daily deaths since the last complete weekly report have been as follows:—

	Cholera.	Diarrhœa.
Sunday and Monday, November 11th and 12th, together	10	2
Tuesday, Nov. 13.....	11	3
Wednesday, Nov. 14	—	—
Thursday, Nov. 15 ...	—	—
Friday, Nov. 16	—	—
Saturday, Nov. 17 ...	—	—

THE COUNTRY.

The Registrar-General directs attention to the fact that the epidemic has "far from disappeared" from the large towns it has visited. During the week there were 82 deaths in Dublin, 36 in Edinburgh, and 14 in Liverpool. In Newcastle and some other towns the deaths are diminishing. The annual rate of mortality per 1000 was 23 in London, 29 in Liverpool, 35 in Dublin, and 37 in Edinburgh.

EDINBURGH.

The weekly returns issued on Monday, the 12th, reported 19 new cases of cholera, of which 12 were in hospital practice. There had been 8 deaths, 8 recoveries, and 3 remained under treatment. Besides these, 13 cases of English cholera, and 89 of diarrhœa were reported, none of which were fatal.

A terrible outbreak had occurred at Leven, a fishing and sea-bathing village in Fifeshire. There had been 32 deaths in the week, and 6 others were reported on Sunday, including, we regret to say, D. W. A. Kennedy, who had for some time been devoting himself to the relief of sufferers from the epidemic. Again it is said the origin of this outbreak may be attributed to impure water. Other villages in the neighbourhood are also suffering severely.

THE PUBLIC HEALTH OF THE SUMMER QUARTER.

THE Registrar-General has issued his returns for the summer quarter of the present year. We pass over most other particulars, and proceed to notice the state of the public health, which they disclose chiefly as affected by the fatal epidemic which this season has visited our shores. We have already given in our pages the weekly returns of the deaths occasioned by this fearful scourge in the different localities of London, as well as other places; and we have now presented to us the "fatality" which has attended it throughout the kingdom in the months during which it has been the most prevalent.

Before noticing the figures which the report contains we may just give to our readers a quotation from the remarks on the weather, and the atmospheric peculiarities which were observed in the summer quarter of the present year, in contrast with those of the three previous seasons when cholera prevailed. It is observed, that this year—

"The mean temperature of the air in the quarter at Greenwich was 58·9 degrees, which is 1·1 degree below the average of the season in twenty-five years. Each of the three months, but particularly August, was cold. The rainfall measured 7·9 inches, half of which was in September, when the amount was an inch and a half in excess of the average. Mr. Glaisher writes that the weather, which had been warm and fine at the close of the previous quarter, changed to cold at the beginning of July, and in every part of the country rain fell almost daily. From the 10th to the 17th was a period of heat, but from the 18th of July to the 25th of September the temperature was almost constantly low. Rain fell frequently all over the country in July, and in August seriously interrupted harvest work. In the three visitations of cholera in past years there was great atmospheric pressure, high temperature, narrow diurnal range, owing chiefly to high night temperature, defect of rain, wind, and electricity; and in the last of those (1854) a remarkable blue mist was observed, which prevailed night and day. In nearly all these particulars the meteorological character of the present epidemic season is different from that of previous periods when cholera prevailed, but the blue mist has been again visible; it was first seen by Mr. Glaisher on 30th July, and by other observers in the preceding week. Since that time it has been generally present; on some days no trace of it visible, and on other days seen for parts of a day only. It has extended from Aberdeen to the Isle of Wight, and was of the same tint of blue everywhere. This mist increased in intensity when viewed through a telescope: usually no mist can be seen when thus viewed; it increased in density during the fall of rain, though usually mist rises from rain. Its density did not decrease when the wind was blowing moderately strong; it decreased when a gale was blowing, but increased again on its subsidence. Whatever may be its nature, he adds, the fact is very remarkable, that since the cholera period of 1854 this phenomenon has not been observed till the present time."

It appears from the returns that the deaths registered in England and Wales in the quarter ending 30th of September were 116,826, being about one-twelfth part in excess of the average death-rate for the last ten summer quarters, which was 20 per 1000, while this year it amounted to 22. There were 10,365 deaths from cholera, and 9570 from diarrhœa, also due in great part to the same cause. The proportion of deaths, however, was very unequally divided. In London the mortality was 29 in 1000; in the North-western division 27; in the two Northern divisions, and in Wales 22. In other divisions the mortality was low indeed below the average: in the South-eastern it was 18; South Midland 18; in the Eastern 18; West Midland 17; North Midland 18. The same disproportion is found in the large cities of the United Kingdom. The mortality in Birmingham was 19; in Bristol 21; in Sheffield 24; in Manchester 31; in Liverpool 50; in Edinburgh 23; in Glasgow 25; in Dublin 24.

From an examination of these figures it will appear that the increase in the rate of mortality is attributable generally to the prevalence of cholera. In comparing the numbers connected with the different districts and large towns, it will be found invariably that the death-rate was highest where cholera prevailed the most. Thus the mortality of London was 29 per 1000, where the deaths from cholera were 4714, nearly one-half of the total deaths from this cause in England. In the North-western coun-

ties the mortality was 27, where the deaths from cholera were 2022, the next severest infliction, and so in like manner the coincidence may be traced in almost every instance, the death-rate being highest where the epidemic was most severely felt.

There is one other important fact which the registry makes evident—namely, that while the increase in the mortality of the last quarter is due to cholera, the latter has been most extensively fatal in those localities where the sanitary conditions of the neighbourhood have been neglected, and where the water supply has been more or less impure. This has been the case in the East-end of London, in the North-western counties, and other parts, while in places where strict precautions have been adopted and carried out the epidemic has been the least fatal in its effects. Liverpool and West Derby, in contrast with Birkenhead, furnish a striking corroboration of these facts. In the former two places, with a united population of 495,587, the deaths from cholera were 1603, being one out of every 310 persons, while at the latter place, Birkenhead, on the other side of the Mersey, exposed to the same epidemic influences as Liverpool, the deaths from cholera only reached 30 out of a population of 61,420, being but 1 in 2048. The only explanation of this great and striking difference is that at the latter place timely precautions were taken before the epidemic reached them, and afterwards every effort made to arrest its progress. How this was done we can best show by giving the words of Dr. Baylis, the Medical Officer of Health. He says:—

“In addition to ordinary measures, we commenced a system, before its appearance, of deodorizing all the worst middens in the town, on the principle that, if we could destroy the gases of decomposition in the worst parts of the town, we should remove one of the greatest depressants of the vital force; this system was carried out more effectually after the disease appeared.

“I saw the first patient that died, and my friendly connection with all the medical men of the place enabled me to reach nearly every succeeding fatal case. To the friends of each I gave the most urgent instructions, furnished the poor with disinfectants, sprinkled their floors with carbolic acid, had chloride of lime regularly thrown in their and neighbouring ashpits, used carbolic acid in their waterclosets and drains; took, in the first instance, and until the guardians moved, the responsibility of burning the soiled bedding; had all the soiled clothes steeped in chlorine water, and saw that the houses were perfectly cleansed down. Finally the body was partially covered with charcoal, and buried in a few hours.

“By these means the disease, I think, was in most instances stamped out; and I feel sanguine, if there was a proper staff for the purpose, with the necessary power, together with the means of getting at every case attacked, a medical officer, accustomed to his duties, and otherwise competent, would have a good chance of keeping down the malady, where the conditions were not so very bad as to preclude all chance of success.

“I confess, however, with every wish to do our duty, for want of more power, the careless, the drunken, and the stolid poor defeat one occasionally, and then we had, in some instances, a second and a third case in the same house. These, however, were the exceptions.”

There can be but one impression from this investigation—it is, that cleanliness, the use of disinfectants, good drainage, and a supply of pure water, are the best preventives of cholera. It is high time that the attention of all who have influence and authority in our cities and large towns should be given to these things. If neglected we may, no doubt shall, be visited again and again by this scourge, which all so much dread. The Registrar-General warns us of this, and urges the necessity of

immediate precaution. Let our readers weigh well his observations, with which we close this article:—

“It is well known that this epidemic raged around us in France, Belgium, and Holland earlier in the year, and during July it established itself in England, where it put the sanitary defences of nearly every district on the coasts to a test. Indeed, the cholera matter (Cholrine) has evidently been diffused all over the kingdom; for in every county, except Herefordshire and Rutlandshire, death from cholera have been registered, and diarrhoea has prevailed to such an unusual extent as to imply the existence of some specific zymotic element. It was only, however, when that element was diffused by water, and by the wilful neglect of hygienic precautions, that the mortality became appalling.

“Thus, although the waters are yet by no means free from impurities, the people of London are no longer supplied as they were in 1849 with unfiltered waters contaminated by their own sewers; and the deaths in the districts of the West, North, Centre, and South of London were 1023 by cholera and 1558 by diarrhoea, among 2,430,046 people. Whereas 3691 deaths by cholera and 740 by diarrhoea—that is, 4431 together, occurred in the East London districts among 607,945 people supplied with water, chiefly from the Old Ford reservoir of one company. Deduct these deaths and the deaths by cholera in London are reduced to 1023 while the deaths by cholera in England are reduced from 10,365 to 6,674. Again, of the 2022 deaths from cholera in Lancashire and Cheshire no less than 1603 were registered in the Liverpool and West Derby districts alone. Deduct these deaths, with 2447 more in West Ham (adjoining East London, and supplied with the same water), in Portsea Island, in the Isle of Wight, Southampton, Exeter, with three adjacent districts of South Devon and Swansea, as well as in certain districts of South Wales, and the death from cholera in the rest of England are brought down to 2624.

“This proves that, although the freest intercourse has been kept up between the various parts of the country, the epidemic has only assumed an aggravated form where the defences have been weak and circumstances have been in its favour.”

Respecting the distribution of the 10,365 deaths from cholera over England and Wales in the third quarter of the year, the returns show that no less than 8098, nearly four-fifths of the whole number, were in three districts—London, Lancashire, and South Wales. Of the 4714 deaths from cholera in London, three-fourths—3590, occurred in six registration districts—namely, Bethnal-green, Whitechapel, St. George's-in-the-East, Stepney, Mile-end Old-town, and Poplar districts, containing less than a sixth of the population of London. The entire mortality of these districts in the quarter far exceeded the number of births, and the mortality of this portion of London was much more than double that of the corresponding period in 1865. In Mile-end Old-town and St. George's-in-the-East half the deaths in the quarter were from cholera. Of the 1872 deaths from cholera in Lancashire no less than 1603 were registered in the district of Liverpool and the adjoining district of West Derby, and the 1412 in South Wales 1074 occurred in the four districts of Merthyr, Neath, Swansea, and Llanelly. In Neath more than half the deaths of the quarter were from cholera, and Swansea and Llanelly two in every three of the deaths. A large part of the cholera mortality was in these three quarters—London, Lancashire, and South Wales—that there were only six counties in the rest of England in which the death from cholera exceeded a hundred. These are Kent (extra-metropolitan) in which 226 deaths occurred, chiefly in the parishes near the course of the Thames; Essex, 435, of which 380 were at West Ham; Hampshire 391, 137 of them at Portsea Island; 98 at Southampton, and 98 in the Isle of Wight; 325 in Devonshire, the chief prevalence being at Totnes, Exeter, and Thomas's; Cheshire, 150; Yorkshire, 240, the largest numbers at Goole and Doncaster. In Surrey (extra-metropolitan) Sussex, Durham, and Monmouthshire the deaths from cholera ranged between 50 and 100. In Middlesex (extra-metropolitan), Gloucestershire, and Lincolnshire between 26 and 50. In Somerset the number was 26; in Northumberland 22; in Worcestershire 17; in Staffordshire 16; in Cumberland 14; in Bedfordshire 13; in Cornwall 12; in Warwickshire 11; in Suffolk 10; in Norfolk 9; in Wilts, Derbyshire, Salop, and Buckinghamshire 7 in Herts 6; in Ca

bridgeshire 5; in Dorset 5; in Notts 4; in Oxfordshire and in Leicestershire 2; Berkshire, Northamptonshire, Huntingdonshire, and Westmoreland had only one each; Herefordshire and Rutlandshire had none at all. Of the 9570 deaths from diarrhoea, 2298 were in London, and 2466 in Lancashire. The London districts most severely visited with diarrhoea were Kensington, where there were 181 deaths, and St. Pancras, Marylebone, Islington, Bethnal-green, Whitechapel, Poplar, and Lambeth, each of which had above 100 deaths from diarrhoea. The provincial districts with above 100 deaths from diarrhoea were Liverpool, with 542; West Derby, 338; Manchester, 410 (but only 39 from cholera); Salford, 167; Charlton, 192; Birmingham, 187 (but only 7 from cholera); Leeds, 166 (but only 9 from cholera); Bradford, 120; Sheffield, 117; Wigan, 116; and Bolton, 102. North Wales had but 32 deaths from cholera and 33 from diarrhoea.

THE POOR-LAW MEDICAL INSPECTORSHIP.

On this subject the *Cork Constitution*, of the 9th inst., remarks:—

“Wednesday evening’s *Mail* has the following:—

“We are in a position to state that the Poor-law Medical Inspectorship is still vacant; the statement as to the appointment made recently in a contemporary is premature.”

“We should be glad to be able to believe this, for it would leave room for the hope that some one who had stronger claims on the grounds of distinction and of service (to say nothing of conservatism, which, after its long exclusion, ought not to be altogether disregarded) might be chosen; but we think our contemporary is mistaken. At all events we believe intimation of the appointment was made to the several candidates by the Poor-law Commissioners, and THE MEDICAL PRESS, which, on such a subject ought to be well informed, says:—

“THE POOR-LAW IRISH INSPECTORSHIP.

“This important office has been filled up by the appointment of Mr. Roughan, of Ballinrobe. Not being informed what that gentleman’s qualifications for the office may have been, we append his description of himself in the “*Medical Directory*”:—“Roughan, George F., Ballinrobe, county Mayo, L.R.C.S.I., 1842; L.M. Dub. Lying-in Hosp., 1846; Med. Off. Union Work.; formerly Med. Att. Moycullen, Spiddal, and Outerard Fev. Hosps.; late Insp. Fev. Hosps.” Mr. Roughan is what racing men would call “an outsider,” for we have never heard his name mentioned as a candidate, and he is almost unknown either to the profession generally or Poor-law Medical Officers. He is an L.K.Q.C.P., of August last, never wrote a line worth reading, never held an investigation or adjudicated on a case. But he possesses superior qualifications. He is a Roman Catholic in religion, and is said to be of the extreme national politics.

“To summarise the facts, he appears to possess every qualification which a medical man elected to such a position ought not to have. To any candidate on the list published in a late issue of our journal, or to others not included in that enumeration, Dr. Roughan bears not the most cursory comparison. Many of those gentlemen being of scientific and literary rank, all of them are well known and respected in the profession. The selection is a theme for our political journals worthy of their notice, for they have ample scope for comment in an appointment which stands badly beside that of Professor Croker King’s, the last selection of Sir Robert Peel for a similar post. It looks like one of the most disgraceful jobs ever perpetrated in Ireland.”

“It is certainly an appointment which could not have been expected, and ought not to have been made. A Government can not only gain no credit by it, but draws on itself censure, for which it is imprudent to give cause. A more meagre claim no candidate could be furnished with; and if he has the additional drawback of extreme nationalism in a country which has suffered so much from political fanaticism, it cannot be even pleaded as proof of the desire of Government to deal impartially; for there were among the Roman Catholic ‘Liberal’ candidates men who, while possessing qualifications that would have justi-

fied their selection, were moderate and rational, and had never made themselves obnoxious by either their opinions or the manner in which they maintained them. There were, on the other hand, men of a different stamp, and we should be glad if there was still hope that Government had not stultified itself by selecting one of these. If it has, and that what the *PRESS* writes is true, it has offered an affront to not only every qualified Conservative candidate, but every qualified Roman Catholic candidate who has abstained from identifying himself with a party which has worked great evil to the State.”

We have seen one of the letters sent to the candidates by the Commissioners, and it concludes in these words: “The choice has fallen upon Dr. Roughan of Ballinrobe, who has been appointed accordingly.” It must be remembered that the *Mail* is the Government organ, and probably it got a hint to deny the appointment, and so prevent agitation, on the technical quibble that Dr. Purcell will not really vacate his office until the 12th of December; but although not perhaps technically installed, yet Mr. Roughan is chosen, and appointed. We trust the *Cork Constitution* will see to this.

The large amount of correspondence which we have received in reference to this appointment shows us that an unusual interest exists in the profession with reference to it. In pursuing the theme, we have first to remove the impression which may have existed, and which is alike unjust to ourselves and a large section of the profession, that we desired to suggest that Dr. ROUGHAN was disqualified from holding the appointment or discharging its duties on religious grounds. We know scores of Roman Catholic gentlemen in the profession in Ireland second to none in respect and in the conscientious discharge of their duties; but as we do not hold that a particular form of worship confers special qualifications for the office of Poor-law Inspector, we should protest, as we have done, against any one of them being appointed because he professed a particular creed. This is what has been done, as we believe, in the case before us; and so far from our considering a candidate better or worse for his religion, we condemn in the strongest manner the introduction of such consideration into the question at all.

The issue is whether Dr. ROUGHAN is a better man in education, abilities, services to the profession or the public or judicial acuteness, than his co-candidates, and if not, why is he placed over their heads, in a position which is of the utmost importance to the Poor-law Medical Officers of Ireland? On investigation, we find that he is a Licentiate of the Royal College of Surgeons, of years’ standing, while some of the candidates are Fellows of double that experience; he is a Licentiate of the College of Physicians of four months’ rank, while others are Doctors of Medicine of many years. Of his abilities we can only judge from the fact that he appears to have left no mark whatever of his talents either in or out of his profession in the years in which he has practised. Of his services to the profession be it said that for fifteen years he has stood aloof from every movement intended for their benefit, and has not even deigned to reply to the notes addressed to him on such matters, nor has he even been a subscriber either to the Irish Medical Association or the Royal Medical Benevolent Fund Society.

But better than transcendent abilities, deep learning, or hearty philanthropy, he has forwarded through the back stairs of the Castle an all-powerful talisman. What that may have been we know not. One correspondent

tells us that it was the signet of Cardinal CULLEN; another, that it was the seal of Lord LURGAN, who voted with the Adulamites for the present Government; a third, that it was the friendly voice of the Solicitor-General and Member for Galway; and a fourth, most reliable, that the influence was exerted through a wealthy shopkeeper in Ballinrobe, who had rendered election services to the present Government. No matter whence the influence, the job has been committed, and should be remembered by the profession when the Government candidates next seek their suffrages. What comparison is there between our new Poor-law Inspector and Drs. MARKHAM, EDWARD SMITH, and FARRE who hold somewhat analogous appointments in England?

THE HEALTH OF SCOTLAND.

In the eight principal towns of Scotland, from which returns are regularly compiled, the Registrar records 2297 deaths during the month of October. This is an excessive mortality, since making allowance for the increase of population, it is 295 above the average for the last ten years. No less than 42 per cent. of the deaths were those of children under five years of age. Zymotic diseases caused 29 per cent. of the total mortality. Even this proportion was exceeded in some towns; as, for example, in Paisley, where scarlatina and typhus have prevailed; in Greenock, where there have been many deaths from typhus, and, of course, wherever cholera has obtained a footing. This epidemic has visited most of the towns, Leith suffering most severely, and Paisley the least. 167 deaths were attributed to that epidemic in the eight towns, thus constituting 7·3 per cent. of the total mortality. There was, therefore, an increase of 119 deaths from that disease above those of September. In Leith, the cholera deaths amounted to 34·2 per cent. of the mortality; in Dundee, to 13·8 per cent.; in Aberdeen, to 12·6 per cent.; in Perth, to 8·5 per cent.; in Edinburgh, to 8 per cent.; in Greenock, to 5·8 per cent.; in Glasgow, to 2·4 per cent.; and in Paisley, to 0·8 per cent. of the total deaths; the deaths from cholera in the month being 37 in Leith (in a population under 40,000); 38 and 22 respectively in the far larger towns of Dundee and Aberdeen; 4 in Perth; 33 in the city of Edinburgh; 25 in Glasgow (with more than double the population of Edinburgh); seven in Greenock; and one in Paisley. There were besides 95 deaths from diarrhoea in the eight towns. Typhus caused 122 deaths, or 5·3 per cent. of the mortality; 12·8 per cent. in Greenock. The births in the eight towns, 3309 in number, were above the average, and so were the marriages, which numbered 654. The month was characterised by fine and settled weather, the barometer being high and little disturbed, the mean temperature high and the daily range small, with less rain and wind than usual, and the direction of the latter nearly west. The highest mean temperature was at Greenock, 50·4; and the lowest at Aberdeen, 48·5. At Glasgow and at Paisley the thermometer marked as low as 26 degrees. The greatest depth of rain recorded was at Greenock, 5·27 in.; and the smallest at Edinburgh, 1·20 in.

From these latter figures it may fairly be concluded that there was no connection between the weather and the large amount of zymotic disease. Let the water and drainage be thoroughly investigated.

Notes on Current Topics.

INFIRMARY APPOINTMENTS.

THE Royal South Hants Infirmary has lately witnessed a scene of great excitement consequent on the determination of the Governor to elect two additional medical officers—one as Assistant-Physician, the other as Assistant-Surgeon. There were no less than six candidates for the former, and four for the latter appointment; but these numbers were subsequently reduced to two candidates for each office. According to the *Southampton Times*, the meetings held by the Governors were noisy in the extreme, and reflect little credit upon many who took part in them. It seemed to be the desire on the part of the chairman and a section of the Governors to withhold certain information which was sought by several members of the corporate body, and a very animated discussion ensued as to who among the annual subscribers to this institution was entitled to vote, and how many votes should be accorded to Life-Governors. Ultimately this matter seems to have been ignored by the chairman, and the voting commenced without anything being definitely settled on this important point.

How they were enabled to declare two gentlemen duly and properly elected we are at a loss to conceive. The point at issue should undoubtedly have been settled, before the voting was allowed to proceed. The chairman and those who were anxious not to further the prolongation of the election, already extended, have precedent on their side, but it would have been far wiser that the election should have been postponed than that when the question of the legality of certain measures was raised, it should have been stifled, and those who stood up as champions of what they deemed right, snubbed and insulted.

The Royal South Hants Infirmary is amongst the noblest of the kind throughout the kingdom, and we heartily congratulate Drs. Scott and Langstaff on their success.

Dr. Maul, whose chance when the election of two new candidates was announced, was considered the most likely of success, and whose many excellent qualities would have eminently fitted him for the post of Physician to the Hospital, withdrew, with five other candidates, at an early period of the contest, and we are disposed to ask whether there must not have been something radically wrong in the management of this institution, which witnessed, in a meeting that should have borne the impress of order and good feeling, such a hurricane of clamour and abuse.

THE ELECTION OF SURGEON TO DR. STEEVENS' HOSPITAL, DUBLIN.

THE selection of a surgeon to this hospital, *vice* Dr. Symes, took place on the 15th inst. Of the candidates named by us on a former occasion only two, Dr. Robert MacDonnell and Dr. De Ricci, came to the poll. The retirement of Mr. Butcher, within a week of the election, was announced with some surprise, inasmuch as we understand that he was recommended by the Managing Committee to the Board of Governors for the vacant office, and might anticipate a considerable amount of support. Dr. Robert MacDonnell was chosen by a large majority. It is presumed that Dr. MacDonnell will attach himself to the Medical School of the hospital, in which case his position as Lecturer on Anatomy and Physiology in the Carmichael School will become vacant, as well as the surgeoncy of Jervis-street Hospital, to which he is at present attached.

PROGRESS.

THE end of Dr. Mary Walker's visit to London—her speech in palliation of want of female virtue at the Social Science Congress—her anti-feminine costume, and her war medals, puffed and belauded by a medical contemporary, is apparent in the announcement in the same column of an intended lecturing exhibition by the American medical nondescript. We most earnestly trust that respectable medical men will show an example to the public and the organ of their profession in discountenancing such a proceeding. May we humbly suggest an attractive title for the delicate young lady's entertainment? *Why not? or Clitoridectomy and its uses.*"

POOR-LAW GUARDIANS AND THEIR MEDICAL OFFICERS.

WE noticed a few weeks since the attempt made by the Guardians of the Strand Union to evade the spirit of humane legislation in reference to the Poor-law by a pretence of adhering to its letter, and under colour of providing a Resident Medical Officer for their Workhouse, to compel their present Medical Officer, Dr. Rogers, to reside permanently in the Workhouse. It need scarcely be mentioned that such an arrangement would be entirely ruinous to Dr. Rogers' private practice, and if carried out it would necessitate his resignation of the post he at present holds, and this is evidently the very object which the guardians wish to accomplish as a sort of punishment to that gentleman for his honourable and praiseworthy endeavours to ameliorate the condition of the sick poor under his charge. It will be perceived, however, that the Poor-law Board has taken some steps in the matter, although it confesses itself in a state of doubt as to the management of the medical department of the Poor-law system. In the mean time the blow aimed at Dr. Rogers has not yet been struck, and if the Poor-law Board is really the protector of the poor, and if it is sincere in its professions to improve the condition of the sick, it will not allow the guardians to pursue the course they meditate; but we have very little confidence in the Poor-law Board, so far as justice to our profession is concerned.

DR. PHILIP BEVAN, Professor of Practical Anatomy in the Royal College of Surgeons in Ireland, has resigned the Surgeoncy of Mercer's Hospital, Dublin, and Dr. Edward Stamer O'Grady has been appointed in his place.

NOTES OF LONDON PRACTICE.

(FROM A CORRESPONDENT.)

THE chief notes of London practice at present have reference to a new mode of treating cancer and cancerous tumours by injection of acetic acid—a plan entirely different from one advocated by Professor Simpson, of acting on such masses with chlorides and other caustics. If the new surgical proceeding succeed as expected, it may help to settle the long-discussed and vexed question whether cancer is a simply local or an entirely constitutional disease. Dr. Broadbent, who proposed this method at the recent meeting of the British Medical Association, as we pointed at the time, has had some very interesting cases to support his hypothesis, that as acetic acid in the familiar microscopic slide has the power of dissolving or altering the cancer cells, without dissolving simple albumen, some forms of cancer may disappear probably or become absorbed in such dissolved shape, not malignant, and possibly pass off by the depurating glands or lungs without doing harm. There seems no doubt that some malignant tumours cannot be diagnosed by such cells, and some with such cells are on the other hand not malignant, but the present idea is one of great interest.

The opinion that cancer is more a local than a constitu-

tional disease gains ground in hospitals, or, perhaps at first local, and then unfortunately becoming fatal, when absorbed into vital organs like the liver or lung. The experience of the Cancer Hospital, as explained by Mr. Weedon Cooke, is rather of an opposite kind—viz., that the disease is altogether constitutional.

The trial of Risk Allah, in Belgium, for a supposed murder, has given rise to several disquisitions of a quasi sensational kind, written by London detectives in the cheap newspapers; but from the first, almost, it was apparent to any one who read the evidence in the *Debats*, that it was a case of suicide. Everybody was struck, all through the trial, with the different mode of conducting such trials in Belgium and in England. A few other points were curious and new. One, that a pistol or gun fired very near the body produces very little noise, as also a gunshot wound usually black. A very small thing—namely, the position of the arms under the bedclothes, was supposed to argue at first there had been murder committed. We almost fear in London, as in the case of Smethurst, no ulterior evidence would have cleared this up, if the prisoner were not permitted to speak. The bullet went right through the head from the angle of the jaw, the head lying on the pillow outside the bedclothes; the recently discharged gun of the supposed murderer on the ground. All this was given in evidence in a very solemn sensation manner by the surgeon first called in. The case is given at some length in the *Medical Times*, but this and other journals copying the *exparte* reports of the "Telegraph," omit the essential fact that the prisoner at once explained this solemn evidence, and obvious murder, and the arms under the bedclothes, and the new turn the case had taken of decided murder, by simply stating that when he and the waiters of the hotel broke into the apartment, perceiving the smell of gunpowder, his first impulse (the prisoner's) was to take up the hand to feel the pulse, being a medical man, but there being none, he replaced the arm under the bedclothes himself, in the ordinary appropriate manner of any dead corpse, and it was a long time after the surgeon arrived, and took the notes for evidence before alluded to. The waiters and women of the hotel at once remembered the occurrence to be as the prisoner stated. The case for murder broke down at this point. The case reminds one rather of the murder where Sir Astley Cooper, from the nature of the wound, gave it as his opinion that the murderer was left-handed, which proved to be a fact. The *gaucherie* here was on the part of the Belgian surgeon. With a perversity rather saddening, various of the journals still uphold the view that, as the supposed murderer in the Belgian case was a medical man, and a considerable sum of money was likely to revert to Risk Allah, the verdict of the jury is doubtful, but nothing can be more absurd.

The London Hospital Theatres have been enlivened of late by the appearance of a veritable female doctor in bloomer costume, who by a *circumbendibus* of the *Lancet* is supposed to wear braces, and dress in many or all ways as a medico of the ordinary sex. It is said Dr. Mary Walker practised medicine in New York for five years, and then volunteered for the Federal Medical Service, and served three years with the army of the Potomac. Accustomed as we have been to the calm presence of Miss Garrett, Licentiate of Apothecaries' Hall, at operations, the appearance of Dr. Walker has not been as appalling as might be supposed. We cannot help thinking and believing that both ladies out of their place. We have before now, indeed, chronicled instances where, from innate modesty, one of these ladies, and more than one of Miss Nightingale's band, have had to leave the theatre, the incongruity of certain operations (phymosis in adults to wit) was so ir-reversible.

THE Spanish Consul at Malta has informed his Government that a contagious epidemic disease has appeared among cattle coming from Tunis.

ADDRESS DELIVERED
BEFORE THE
ULSTER MEDICAL SOCIETY,
NOVEMBER 3, 1866.

By Dr. DRENNAN,
PRESIDENT OF THE SOCIETY.

At a meeting of the Council of the Ulster Medical Society, held on Wednesday the 7th instant, it was formally proposed and seconded, and unanimously resolved, that the President be requested to permit the publication of his Address.

GENTLEMEN,—In conformity with a custom which has been generally, if not invariably observed, I proceed to address to you a few remarks at the commencement of our Winter Session. Whilst by no means affecting originality, or aspiring to the dignity of an Inaugural Discourse, these may serve to direct the attention of our more recently elected members to the principal objects of this Society, and the best means of effecting them.

I have already taken the earliest opportunity of expressing my sense of obligation for the honour of being appointed your President for the current year, and I need now merely repeat that it was an honour quite unsolicited on my part, but only the more prized for its being spontaneously bestowed. I should have sincerely rejoiced if some more distinguished member of the profession had been at this time selected for the office—not only for the increased dignity to have been thereby reflected upon it, but for the substantial benefits which talent and influence installed in this chair might have conferred on our Association at a somewhat critical period of its existence.

You are aware, gentlemen, that this society, judging from the decrease in the number of its subscribers and the diminished attendance at its meetings, has fallen off somewhat of late from the position it formerly held, and which, from its designation as the "Ulster Medical," it would even seem called on to assume. On the causes of this declension I shall not enter, if for no other reason than because I am really very imperfectly informed as to their nature and extent. Amongst them, undoubtedly, cannot be reckoned any want of ability or energy on the part of my predecessors in this chair, or the other official members of the Society. Nor can I for a moment suppose that there has been, at any time, a lack of inclination amongst the practitioners of this locality to maintain an institution so capable of diffusing professional information, and advancing their own claims to confidence and respect. Let us conclude then that our society has been merely suffering of late from a little temporary "Asthenia," indicative of no serious organic disease or senile debility, and easily removable by some simple measures for imparting additional warmth to its members and increasing the force of its cerebral circulation. The copious supply of new blood infused into it during the present year will doubtless contribute much to its convalescence, whilst we have already had proof, in the proceedings of our Summer Session, that there is no decline whatever in the vitality of the *old*.

Amongst those who formerly co-operated with us, we have to lament the recent death of a respected associate in the person of Dr. Halliday. He died comparatively young, and the arduous duties of Dispensary Medical Attendant, which he so sedulously discharged, and which had latterly pressed very heavily upon his strength and spirits, hastened in all probability his passage to the grave. He filled for several years the office of Treasurer to the Clinico-Pathological Society, and took a frequent part in its discussions, and those of the *older* "Medical." In token of respect for his memory the members of this Society attended his funeral, and his professional and personal worth was still more vividly attested by the thronging together of his poorer friends, as the earthly remains of their kind "District Doctor" were carried to the tomb.

With the exception of this loss on our part, and some others less recent, we meet here to-day under circumstances specially propitious. The room, which by the kindness of the Hospital Committee, had been for many years devoted

to our exclusive use, has been of late partially applied to other purposes. For this restriction, however, we have received in the convenient and capacious apartments in which we this day assemble for the first time a much more than equivalent return. In them we possess not only a large, well lighted, and commodious place of meeting and reading-room, but space sufficient for the suitable arrangement of our collection of pathological portraits, casts, and specimens. Whether it may be advisable hereafter to transfer our library also hither must depend on circumstances, and will be a question for future consideration. The Society must feel truly grateful, and will, I presume, express its acknowledgments to those to whom we are indebted for this very valuable endowment. To Mr. Charters, the munificent donor of this wing of the hospital, to the Hospital Committee, who have conceded this portion of it to our use, and to our worthy Vice-President, Dr. William MacCormac, at whose suggestion and by whose intercession it was mainly obtained—to each and all of these we are certainly deeply indebted, and owe the expression of our warmest thanks.

Among the other valuable results of this seasonable acquisition, we have now that portion of our revenue, recently expended on the rent of hired rooms, at our disposal for other purposes. Of these there is surely none more eligible, none more urgent, than the improvement of our defective library, by the addition to it of books of sterling professional value. One of the primary objects of the Society, as stated in its fundamental rules, is "to afford its members increased facilities of consulting the best medical works and periodicals," but in consequence of restricted resources, that object has been of late very imperfectly accomplished. A substitute for the purchase of new works was attempted by the hiring of them from a lending library. But however a means of this kind may answer as a supplementary one, or for the procuring of publications of comparatively trivial interest and the lighter literature of the day, it affords very inadequate facilities for the serious study of elaborate treatises, and none whatever for the consulting of voluminous and systematic works. For such purposes a permanent and progressive library is absolutely necessary, and most of us can only hope to enjoy such a possession by holding it in common. At no time more than the present has there been required on the part of every member of our profession, who wishes to promote its advancement or uphold his own credit, an acquaintance with its scientific history and actual progress. The spirit of free inquiry, that motive spirit of the age, is acting in no field more energetically than that of medicine. Deny or deprecate the fact as we may, medical theory and medical practice, too, are at present in a state of transition. No doctrine, however venerable, no statement, however often attested, but must submit now to fresh scrutiny, and to the confirming, destroying, or emendatory hand of the strictest criticism, armed with new instruments of research. The number of able and ardent inquirers in every department of our art was never before so great, and the press teems with the results of their investigations. He who ignores these results, who in the midst of all this sifting of old opinions and seeking for new truths, rests satisfied with the traditionary formulas of medical faith, will soon find he is *behind the time*, and has forfeited his claims to consideration even as a "practical man." His shallow dogmatism may impose upon others yet more ignorant than himself, but he will be held in no esteem by the only real judges—the well-instructed members of his own profession. I say, then, that were this Society merely an economical instrument for communicating through books and periodicals the accessions to medical knowledge that are continually being made, and the course of the ever-flowing currents of medical philosophy, it would be amply deserving of our support. We have here a comfortable reading-room open at convenient hours; we have secured the services of a competent librarian, at hand most of the day for the receiving and giving out of books; a complete catalogue has been lately drawn up, and a more satisfactory mode of circulating the journals adopted. In short, for the formation and maintenance of a useful and creditable medical library, we want nothing now but sufficient funds and their judicious expenditure.

But this Society was not intended to be merely a Book-Club. It has important objects besides that of furnishing us with other men's opinions, however valuable these may be. It is meant for the expression, discussion, and diffusion of our own. The comparatively short period of time to

which our meetings are limited is an obstacle to the introduction of theoretical questions requiring lengthened exposition or prolonged argument, but has been found quite sufficient for the reporting of interesting cases, for the exhibition of pathological specimens, and for instructive commentaries on both.

Medical experience is constantly presenting, if not absolutely new subjects for notice, though such not unfrequently occur, at least novel relations of, and inferences from, the old. Every busy practitioner meets with striking and suggestive cases, with points in pathology, or with results of treatment worthy of record and subsequent reflection. To determine the true worth and bearing of such incidental facts nothing can more effectually contribute than the submitting of them to minds of kindred pursuits, whilst at the same time free from the bias which so often unconsciously attaches to the original observer. "Truth, like a torch, the more its shock it shines." Its flame gathers strength, and its light flashes farther for the motion, whilst in its swift passage from mind to mind it throws off the adventitious particles which at first obscured its lustre, and becomes at length a pure effulgence—a *lumen siccum* never afterwards to be extinguished.

An acute, though unpremeditated question, an apt analogy or a pertinent counter-instance, may often aid effectually in defining a dubious fact or dissipating a nebulous hypothesis. Nor is the utility of our discussions to be measured by their more immediate or obvious results, or the length to which they are carried. Short suggestions may be thrown out in the course of them to be afterwards worked upon and tested, tacit assumptions may be quietly corrected, or a new importance suddenly imparted to some half-forgotten observation or train of thought. In a word, the simultaneous action of different minds on the same subject is often the shortest, simplest, and most decisive means of ascertaining its real import and value. As a criterion it operates "tuto et cito," and here, at least, we will anticipate always also "jucundé." The differences and the concurrence of the inquirers alike aid in the discovery and development of truth. The one stimulates the desire, the other strengthens the capacity for attaining it, whilst the very seeking of it in common augments the sense of its importance. On disputed points of theory or practice, a society like ours has, of course, no pretensions to be considered an ultimate tribunal. As a court of opinion, however, we may sometimes properly assume the functions of a grand jury, and quash the bills submitted to our scrutiny, or remit for further trial. Perhaps an occasional interchange of single papers or collected transactions between ourselves and other kindred societies might prove conducive to the common objects of both.

On questions of professional etiquette and personal difference—should such unfortunately occur—our council might, I think, advantageously continue to occupy the place filled by that of a former society, and act as a court medical for their amicable arrangement. All who have the dignity of the profession at heart would certainly prefer a reference to some such friendly arbitration to exposing their personal grievances or dissensions before an indifferent public. On this subject, I may observe that the code of medical ethics drawn up by the Belfast Medical Society is still extant, and worthy, I think, of adoption by our own.

In the relations of our profession with the public at large such a Society as this might, it appears to me, render material service to both parties, and occupy a higher position than ours has yet held.

Whilst, gentlemen, no other body of citizens, I assert, confer such an amount of public benefit in so liberal and self-denying a spirit, we medical men are undoubtedly deficient in some of the chief elements of popular consideration. Very few of us are affluent—most of us of comparatively small means, and this "res angusta" must tend to impair the social estimation in which we are held, especially in a community where wealth is not only the general object of exertion, but too apt to be esteemed its highest reward and the prime standard of value. Nor can we boast of imposing titles, or corporate political influence. In short, we want all the coarser elements of power, and it is therefore not surprising if we be sometimes treated as the weak. Now, the mere associating of ourselves together, be it only for scientific objects, must strengthen at least our moral claims to consideration by exalting our character as a class. But it may do more than this: By cultivating among ourselves

a certain laudable "esprit de corps," and common methods of action, it will enable us, on the good old principle of "vis unita fortior," more effectually to maintain our professional status and defend our professional rights, should either become the object of depreciation or attack.

I by no means wish to convert the Society into a trades' union for the maintenance or advance of wages—though trades' unions themselves have their strong points of justification. I would not even desire much of our time to be spent in discussions on the subject of fees. But even here, inasmuch as we are all, I presume, quite willing, individually, to accept such offerings, it might not, I think, be any-wise inconsistent with professional delicacy if, as a united body, we should come to some understanding as to their suitable amount. There is an unpleasant ambiguity about that polite Latin word, "Honorarium," and an occasional disagreeably close translation of it by our patients, which an authoritative definition of the term by ourselves might help to amend. Our junior brethren at least might find it not unfrequently desirable to be able to refer for an ample meaning to a recognised *medical* dictionary.

On matters of public hygiene and medical police, this Society might, I conceive, sometimes originate valuable suggestions, or at least offer valuable advice when consulted by our municipal or other local authorities. As a sort of standing counsel on such questions, its services if required would, I am sure, be always gladly rendered. That there is no disposition to allow its due weight to professional opinion on matters regarded as within its province, I may refer to a late occasion where an important point in the administration of the adjacent hospital was mainly determined by an appeal to medical authority.

It is quite true that on some subjects in sanitary science—as, for instance, the preventive and curative management of the formidable epidemic now within our boundaries—we may fail to be unanimous, and our deliberations may thence yield in their result but an uncertain sound. But we should not, in my opinion, fear to let such discordance be known. "Doctors differ," no doubt; it is only theologians and lawyers who always agree—but we seldom differ for difference sake, but simply because the subjects on which we are called on to pronounce are often of a kind in which positive knowledge is at present unattainable. On such matters difference of opinion amongst "experts" implies serious grounds for hesitation, and the proper inference to be drawn from it is the propriety of caution in action. The warning thus conveyed may be in itself most salutary, if only by discrediting the more presumptuous counsels of the sciolist and the charlatan.

With regard to quackery itself, whether public or private, I do not believe it can ever be extinguished, or even materially repressed by legislative enactments. It is a necessary consequence of the imperfections of our art—a natural expression of impatience with them. Health is a jewel of such inestimable value—in such universal request—that when the mine of knowledge proves unable to furnish it, the gutters of ignorance and imposture will ever continue to be raked in the futile hope of finding it there. The best, if not the only means, in my opinion, of discountenancing the unprincipled empiric, is to maintain and try to elevate still further our own character, individually and collectively, for candour, philanthropy, and science. Those, however, who may wish to enforce the law against unqualified practitioners, will find facilities for doing so in the Medical Protective Society, which is amalgamated with our own.

I have now, gentlemen, sketched feebly, and, I fear, tediously, the nature and purposes of our Society, as I conceive they are or might become. I had intended a discourse of another kind, and haply of more general interest; but on reflection it seemed that, at this particular juncture in the lifetime of our association, it might be expedient to recal the objects of its existence, and attempt to impress them afresh on the attention of its godfathers and guardians. Certainly without a lively sense of these, and a steady conviction of its capacity for effecting them, we are little likely to secure for the "Ulster Medical Society" length of days or energy of action. But *possunt qui posse videntur* and worked and wielded with a will we shall make of it, I feel assured, a powerful instrument for advancing knowledge, promoting friendly feeling, and maintaining professional credit. Even in aiming at such ends, we shall not only merit the support of our own body, but become entitled to the esteem and countenance of the general public.

Correspondence.

PROMOTION IN THE ARMY MEDICAL DEPARTMENT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Accept my thanks for the information given in your last publication on the subject of promotion (or rather want of promotion) in the Army Medical Department. I believe it to be the duty of medical teachers, and editors, to keep the rising generation fully informed on the public services; and yet not one of the introductory lectures of 1866, delivered in England, contained an allusion to the subject, wherein I consider them reprehensible, as they should be as pilots pointing out the rocks and shoals.

From a late Parliamentary return, I find forty years to be the allotted time for a young man, now joining, to obtain his promotion, or in reality never, as by her Majesty's warrant of 1858, sec. 11., all surgeons-majors, surgeons, or assistant-surgeons, shall be placed on the retired list when they shall have attained the age of fifty-five years. The average age for young men to enter the service is twenty-five years, to which add forty, and they are ten years beyond the age at which they must retire. Now, according to the above, there can be no more surgeons, all assistant-surgeons having to retire as assistants; neither can there be any more surgeons-majors after twenty years full-pay service, as they must be first surgeons before becoming surgeons-majors.

It is clear that the department is drifting into a glorious state of confusion on the subject of promotion, and should we only live a few years we shall see no rank save and except that of the "assistant-surgeon."—Your obedient servant,

PATERFAMILIAS.

A CANDIDATE FOR THE OFFICE OF CORONER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I beg to inform you that I am a candidate for the office of Coroner for the City of London. I see other gentlemen's names mentioned in THE MEDICAL PRESS AND CIRCULAR, but mine is not, which is calculated to injure me.

I have been from my infancy connected with the City, being the son of a member of the Spectacle Makers' Company (the late Joseph Dunn, of Gray's Inn, Barrister), who held, in his early days, a city appointment himself. I was a boy at the City of London Schools, and a student of Guy's; since which I have been in India, some years in extensive practice in Kent, and for the last six or seven at the West-end.—I am, Sir, your obedient servant,

J. P. HOLT DUNN.

HOLT'S INSTRUMENT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I hope you will do me the favour of correcting a mis-statement made by Mr. B. W. Richardson. Mr. Holt's instrument is his own, and not Perré's. If they are the same instrument, why should Mr. Holt's be generally adopted by the profession, at least by most of the first practitioners both in England and this country, while Perré's, which has been known for many years previously, has been completely rejected? The idea, Mr. Holt himself acknowledges he derived from Perré's. The practical and useful, I might say invaluable instrument, now so generally used, the profession owes entirely to Mr. Holt.—Yours sincerely,

PHILIP C. SMYLY.

JONES' CHART.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As I see that in your paper of last week you allude to

my "Chart of Medicinal Preparations," just published, write to apologise for some *errata*, on the part of the printer which occur in it, in the spelling of some names of drugs which shall be corrected in any future impressions.—Yours faithfully,

H. N. JONES.

THE MEDICAL CLUB.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Through the kindness of Sir Charles M'Grigor, I beg to inform your readers that the business of the above Club will, in future, be conducted at 17, Charles-street, St. James' S.W., where all communications are to be addressed until further notice.—I am, yours, &c.

LEVY MARSH, M.D., Hon. Sec.

REDUCTION OF DISLOCATION UNDER CHLOROFORM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—A little discussion is going on in the *British Medical Journal* as to an alleged novelty in the treatment of dislocation by manipulation under chloroform. It is a curious but melancholy fact that our London weeklies now chiefly hear but one side of questions, especially that which suits some small book-shop *clique*, or popular prejudice. This reduction of dislocation under chloroform is no novelty; it is described in detail in my small book on chloroform, as I saw it tried in a dozen cases, at Guy's especially.—I am, &c.,

CHARLES KIDD, M.D.

P.S.—I wish you would let me say, as regards chloroform, that it is entirely erroneous that there is a sinking of pulse during ovariotomy, as supposed by Dr. Richardson, from a theory of his as to its action. As also that the ether spray causes sloughing of the abdominal wound, and does not lessen the chief agony of the operation, that of tearing the adhesions in the peritoneum.

APPOINTMENT OF A MEDICAL INSPECTOR.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your most forcible remarks on the recent appointment of a Medical Inspector must command the entire approval of all right-thinking members of our profession, however otherwise divided by education, social status, religious belief, or political opinions. The sad and degrading spectacle has been openly manifested of men holding a responsible and elevated position not only passing over the best qualified candidates for an important office in the service of the country, but actually selecting a person who can hardly be said to have any suitable qualifications at all, and only remarkable, as you justly say, for the possession of those which the occupier of such a post "ought not to have." That a gross and disgraceful job has been perpetrated by a public board is unquestionable, but what must be thought of the political or *ex-officio* members of that body when it is known that a recently-appointed Prince of the Roman Church, moved by private influence, put his *imprimatur* on an unknown candidate, while there is good reason to believe that Tory officials were only too delighted to accept the recommendation, however unpalatable, in the wretched, and, I trust, delusive hope of a future *quid pro quo*, when some forlorn Government candidate for senatorial honours shall have reason to question the conscientious support of a Catholic constituency? Every enlightened member of our profession will rejoice when the best and wisest, irrespective of creed and politics, obtain the highest place; all should feel humiliated when the reverse prevails.—Faithfully yours,

M.D.

I enclose my card.

Notices to Correspondents.

Dr. B. W. Foster.—We shall be glad to have the communication as soon as possible. Not more than a page and a half for December 19th. The advertisement will be done unless the situation is already disposed of.

Dr. Emerson J. Reynolds.—Letter received, and shall be inserted.

Dr. Fulton.—Address altered as desired.

Dr. Sandham, Cork.—The communication on *Paradisation* is in the editor's hands for revision.

Dr. O'Rourke.—You will find further information on the "disgraceful job" respecting our comments on which you honour us with the title of "infamous." We have repudiated the charge of religionism; as for that of loyalty to the Crown and State, we are content to bear the ignominy of it. If we desired to administer the smartest reproof in our power for the style of your letter, we would simply publish it and give Dr. Roughan its full benefit.

Lex.—An "obsolete monopoly" may be defined as a protective provision which is not in accordance with the progress of free education, and which is rendered effete by the advance of opinion on the subject. We think that the monopoly of education for the degrees of the Queen's University by three Queen's Colleges answers this definition. Nothing of the sort exists in sister universities.

Medical Student.—The Irish Poor-law qualification is a diploma in surgery, a licence in medicine, and a diploma in midwifery. The Queen's University M.D. and M.Ch. are fully recognised and accepted.

Inquisitor.—The appointment of Resident Physician to an Asylum is in the gift of the Government. The salary varies according to the size or accommodation for patients. The Richmond is over £500; the Cork over £400 a year; the lowest salary is £260. The Resident Physician has spacious and well furnished apartments, with fire, light, and washing, a generous supply of physic for self and family, and an abundance of vegetables. Though the Government appoints, still the influence of an M.P. is all-important, and generally decisive when locally connected with the institution. Also the recommendation of the governors, if they have had any knowledge or experience of the candidate's abilities.

Subscriber.—The prescription for S. Ogden's Chlorodyne is taken from the *Pharmaceutical Journal* for May 1, 1862, as follows:—"Chlorodyne.—In reply to a correspondent we give Dr. Ogden's formula for Chlorodyne, published in the *Chemist and Druggist*, January 14, 1860.—Take Chloroformyl f3vj ; Ether. Chlor. f3i ; Tinct. Capsici, f5ss ; Olei. Ment. Pip. gr. ij ; Morphia Hydrochlor. gr. viij ; Acid Hydrocyanici (Sch.) gr. xij ; Acid Perchlorici gr. xx ; Tinct. Cannabis Indicæ f3i ; Theriacæ f3i . Miscæ."

Appointments.

DRUMMOND, Mr. A., has been appointed Resident Surgeon-Accoucheur to the Birmingham General Dispensary, vice Thorp, resigned.

FRYER, Dr., L.K.Q.C.P.I., has been appointed Assistant House-Surgeon to St. Mary's Hospital, Manchester.

LOYD, R. R., M.R.C.S.E., has been appointed House-Surgeon to the Peterborough Infirmary, vice H. R. Smith, L.R.C.P.Ed., resigned.

LUSH, J. A., M.D., has been elected Mayor of Salisbury.

RICHARDS, J. P., M.R.C.S.E., has been appointed Assistant Medical Officer to the Devon County Hospital.

SIMMONS, B., M.R.C.S.E., has been appointed Certifying Factory Surgeon for the District of Wootton-under-Edge, vice E. A. Kingsley, M.R.C.S.E., deceased.

SMITH, W. T. Y., L.R.C.P.Ed., has been appointed Medical Officer to the Barnsley Union Workhouse, vice R. Ibeson, M.R.C.S.E., deceased.

WATKINS, W. L., L.K.Q.C.P.I., has been elected Medical Officer, Public Vaccinator, and Registrar of Births, &c., for the Drumlish Dispensary District of the Longford Union, vice R. C. Gwydir, M.R.C.S.E., resigned.

STRANGE, A., M.R.C.S.Edin., has been appointed one of the Assistant Medical Officers to the Gloucester County Asylum.

WRIGHT, J. H., M.R.C.S.E., has been elected Surgeon to the Halifax Infirmary.

DAVIS, R. H. D., L.R.C.S.I., has been elected Medical Officer, Public Vaccinator, and Registrar of Births, &c., for the Killybegs Dispensary District of the Glenties Union, Co. Donegal, vice D. Deveny, L.R.C.S.Ed., resigned.

BIRTHS.

BARKER.—On November 6, at Ivy Lodge, Hornsey-road, the wife of A. J. Barker, M.D., prematurely, of a daughter, stillborn.

DICKSON.—On November 5, at Trinity-square, Tower-hill, the wife of W. Dickson, M.D., R.N., of a daughter.

WESTMACOTT.—On November 1, at 19, St. Mary's-terrace, Maida-hill, the wife of J. G. Westmacott, of a son.

ATWOOD.—On the 24th ult., at Clarendon-road, Notting-hill, the wife of W. A. Atwood, M.R.C.S.E., of a son.

BRITTON.—On the 4th inst., at Acacia-road, St. John's-wood, the wife of W. S. Britton, M.R.C.S.E., of a daughter.

COUCH.—On the 25th ult., at Bodmin, Cornwall, the wife of T. Q. Couch, M.R.C.S.E., L.S.A., of a daughter.

FRITCHETT.—On October 24th, at Rastrick, Yorkshire, the wife of Henry Fritchett, M.R.C.S.E., of a son.

ROE.—On November 6, at the Royal Naval Hospital, Plymouth, the wife of T. A. Roe, M.D., Surgeon-Superintendent British Hospital, Callao, of a son.

DUNBAR.—On the 28th ult., at Blackburn, Lancashire, the wife of R. P. Dunbar, M.D., of a son.

TODMAN.—On the 12th of September, at Port Elliott, South Australia, the wife of James Todman, Esq., M.D., of a son.

MARRIAGES.

LIVINGSTON-STEEL.—On November 1, at Glasgow, John Livingston, M.D., of Greenlaw-place, Glasgow, to Isabella, youngest daughter of the late John Steel, Esq., of Glasgow.

BECKER-KIRBY.—On October 25, at the Parish Church, Chestport, Monmouthshire, H. F. V. J. Becker, M.D., of Cartilian House, The Lizard, Cornwall, to Mary Julia, daughter of the late John Kirby, Esq., of Talgarth, Monmouthshire.

COLLINS-BULL.—On November 3, at Epsom, John H. Collins, F.R.C.S.E., District Surgeon, East India Railway, to Mary Ann, second daughter of the late D. Bull, Esq., of Marston, Beds.

STUART-HEDOER.—On November 6, at St. Mark's Church, Woolston, Hants, John Stuart, Assistant-Surgeon, 78th Regiment, to Sarah Frances Frashard, eldest daughter of P. Hedger, Esq., of Woolston.

DEATHS.

BOND.—On the 1st inst., H. H. Bond, M.R.C.S.E., of Richmond-road, Islington, aged 61.

ARNISON.—On October 27th, at Stanhope, Durham, L.R.C.P. G., Edin., aged 62.

ASTLE, AMBROSE.—On October 26, Ambrose Artle, M.R.C.S.E., of Iron Market, New-castle-under-Lyne, aged 75.

BURNELL.—On October 31, at Beaconhill House, Exmouth, Devon, W. H., M.D., Deputy-Inspector-General of Hospitals, aged 71.

HUNTER.—On November 2nd, Mayor of Margate, at Margate, G. Y. Hunter, M.D., F.R.C.S.E., J.P., in the 72nd year of his age.

LESLIE.—On October 31st, at Cowley House, near Exeter, A. Leslie, Surgeon R.N., in his 90th year.

THOMPSON.—On October 28th, at Aberdeen, of Whitehaven, John Thompson, M.D., aged 45.

CLARKE.—On the 27th ult., Alfred Clarke, M.R.C.S.E., of Clarence-street, Gloucester, aged 46.

ARTHUR.—On the 29th ult., at Balcastle, James Arthur, L.R.C.S.Ed.

IRELAND.

CURREY.—On November 3, at Lismore, Ireland, the wife of Dr. Currey of a son, stillborn.

WARDEN.—On October 31, at 272, Hagley-road, Edgbaston, Birmingham, the wife of C. Warden, M.D., of a son.

SCOTT.—On October 21, at Musselburgh, N.B., the wife of T. R. Scott, M.D., of a son.

FILSON.—On October 27, at Portaferry, Co. Down, Alexander Bell Filson, M.D., aged 69 years.

OBSERVATIONS ON PRACTICAL MEDICINE.

By Sir HENRY MARSH, M.D., Bart.,

PHYSICIAN IN ORDINARY TO THE QUEEN IN IRELAND.

Edited by J. STANNUS HUGHES, M.D., F.R.C.S.I.,

PROFESSOR OF SURGERY IN THE ROYAL COLLEGE OF SURGEONS IN IRELAND;
SURGEON TO THE LORD LIEUTENANT'S HOUSEHOLD.

OBSERVATIONS ON A PECULIAR CONVULSIVE DISEASE
AFFECTING YOUNG CHILDREN, WHICH MAY BE TERMED
"SPASM OF THE GLOTTIS."*

(Continued from page 289, vol. 46, Second Series.)

DOCTOR JOHN CLARKE, in his "Commentaries on the Diseases of Children," has described a spasmodic affection which he terms "a peculiar species of convulsion in infant children." This disease appears to consist primarily in spasm, occurring suddenly, and affecting the muscles of the glottis; as it increases in severity, other muscles, particularly those of the fingers and toes, become progressively engaged; and ultimately, if neglected or mistreated, leads to severe and universal convulsions. This affection, though alluded to and described by several, is yet not generally known or recognized; and the principles of treatment, not always correct, have obtained but little notice or attention. To supply this deficiency, and to bring this disease more under general notice, are the objects proposed in this communication.

This infantile affection I at first considered to be of rare occurrence and of little danger; further observation has proved that instances of it are by no means few, and that it oftentimes terminates fatally. I cannot, however, but think that it is to early mismanagement or neglect that its dangerous or fatal tendency may, in several instances, be traced.

From my notes I have selected a few cases: in these, the leading facts only are stated; they, however, are sufficient to elucidate the characteristic features of the disease, and the principles of the treatment. It will be well to look at the disease, first, when it exhibits its mildest and least complicated characters; afterwards to see its severer aspects, and its more frequent complications: indeed, in the study of spasmodic affections, it is important to learn, first, their essential characters, afterwards the functional derangements or diseases with which they are observed most frequently to co-exist; thus, for instance, in the treatment of chorea, if complicated with derangement of the digestive organs, the purgative treatment recommended by Dr. Hamilton will often be effectual; but, if there be no such complication, as observation often proves to be the fact, this mode of treatment becomes worse than useless; it really adds to the disease which it is intended to relieve, and augments the convulsive movements of the muscles; hence it happens that many cases

* The above admirable paper on "Spasm of the Glottis" in children must be looked on by all physicians as one of the most valuable of Sir Henry Marsh's contributions to practical medicine, written as it was at a time when little was known of the true nature of the affection and consequently of its proper treatment; and it is to be regretted that so few of the authors who have written subsequently on the disease have had the candour to award to Sir Henry Marsh the credit he so eminently deserved for having brought the subject so lucidly before the profession.
—J. S. H.

of chorea which have resisted empirical courses of purgative medicines, have yielded speedily to local applications over the origin of the nerves which supply the muscles affected, combined with a decidedly tonic treatment. The spasmodic affection, now under consideration, requires to be studied in the same manner. It stands sometimes alone, no discoverable source of irritation, no other perceptible disease co-existing with it: more frequently, however, it is complicated with painful dentition, with derangement of the digestive functions, with a cachectic state of the system induced by an impure atmosphere, with fever, and occasionally with effusion into the ventricles of the brain; the consideration of these various complications bears most importantly upon the treatment. The case I shall first narrate exhibits the disease in its mild and simple form.

A child, eleven months old, remarkably healthy, and in appearance well thriven, had been for some time affected in the following manner:—It had been observed, now and again, to awake suddenly from sleep in a state of alarm and agitation, to struggle for breath, and, after repeated efforts, to recover from the paroxysm, with a long and sonorous inspiration; the convulsive effort was described to be severe, and the face to become swollen and purplish: these attacks occurred, at first, only on awaking from sleep, afterwards more frequently, sometimes without any perceptible cause, at other times, and more frequently, when she was vexed or was about to cry. On examining the child accurately, I could discover no deviation from a state of perfect health; the pulse and respiration were natural, skin cool and soft, tongue clean, the breath pure, the appetite good, the bowels regular; the alvine excretions exhibited the appearances usual in healthy children on the breast. She was playful and lively, but was startled unusually by any sudden noise; the four incisor teeth had appeared; the gums were neither swollen nor tender.

The treatment consisted in half-grain doses of sulphate of quinine every sixth hour, and free exposure to the open air; the attacks became less frequent, and after some days ceased altogether. She has since (during a period of two years) remained in very good health.

Two other cases have fallen under my observation, in which the disease was confined to an occasional spasmodic affection of the glottis; no other perceptible derangement of function co-existing with this, nor any apparent irritation from dentition; in these, as in that already stated, the disease subsided under the influence of a mildly tonic treatment.

A patient whom I had been attending, happened to mention to me incidentally that her child, about fourteen months old, was in the habit of awaking suddenly from sleep as if alarmed, breathed with difficulty, and made a loud noise like that in a fit of the whooping-cough; she said also, that this occurred occasionally during the day, when the child was cross; she spoke of this lightly, as of an unimportant thing. I requested to see the child; it looked pale and unhealthy; the integuments were soft and flabby; the tongue coated; the bowels relaxed or confined; the stools green and curdy; the child was irritable and nervous, and seemed to suffer from dentition; the extremities were slightly swollen, and the thumbs placed firmly across the palms of the hands. I stated that I thought the child very ill, and that probably convulsions would take place.

Next day I was summoned in haste, and found the child just recovered from a severe paroxysm of general convulsions.

The gums over the projecting teeth were divided; leeches were applied to the temples, cold lotions to the head, and warm fomentations to the extremities; aperient medicines were given; the nurse, whose milk obviously disagreed with the child, was changed; and it was removed from the city to a healthy situation in the country: after one other attack of convulsions, recovery was speedy and complete.

In this case the disease was complicated with derange-

ment of the digestive functions, and also with painful dentition; the convulsive paroxysms, at first partial, increased in severity, and at length became general. The remedies, which appeared to be ultimately and apparently efficacious, were, change of air and change of nurse.

A fine child, twelve months old, remarkably large for its age, had been subject, for four months, to frequent attacks of what the parents called croupy breathing; those attacks, they said, occurred at first only at night and rarely, afterwards occasionally during the day; for some time the child appeared so well that those attacks were disregarded; at length, having increased in frequency and severity, medical advice was obtained; the treatment, which consisted in bleeding, emetics, mercurial purgatives, confinement to a heated apartment, and warm flannels next the skin, was founded on the supposition that pulmonary inflammation existed.

When I first saw the child, the struggle in breathing was difficult and protracted, and the face, during the paroxysm, became quite livid: these attacks, which usually terminated with a loud and sonorous inspiration, were excited by very slight causes, such as sudden noises, the removal of the child from the nurse's arms, or any source of irritation or annoyance; and now, instead of going off as formerly, they were, once or twice in the twenty-four hours, terminated by severe and general convulsions, which had all the characters and appearance of an epileptic paroxysm: after one of those, strabismus remained;* there was also a swollen and puffy state of the extremities, with a spastic rigidity of the fingers and toes; the digestive functions were greatly deranged, and the child looked exceedingly ill: it had been weaned for nearly three weeks; a healthy wet nurse was procured; the gums, rather as a measure of precaution than from necessity, were divided; the temperature of the apartment was lowered, and gradual habitation to the open air adopted; the quantity of clothing with which the child was oppressed, was by degrees diminished, and after a little time, the body was sponged daily with vinegar and water: the child had already been so frequently and copiously bled, that further bleeding was not deemed advisable. Its health improved rapidly, and restricted in nutriment to the nurse's milk, the bowels soon returned to their natural state; the general convulsions ceased altogether, and the attacks of spasmodic dyspnoea became daily less frequent and severe. As a proof of the completeness of recovery it may be mentioned, that a few weeks having elapsed, this child was extensively scalded, and yet no convulsive or spasmodic symptom ensued. The child, moderately covered, almost lived in the open air, and, during the whole process of dentition, a succession of fresh wet nurses was provided. He is now, after the lapse of some years, a fine and healthy boy. In this case, the change of nurse and the substitution of the tonic for the heating regimen were attended with results at once speedy and satisfactory.

A weakly and delicate child, two years of age, had been subject, for some time past, to occasional and sudden attacks of dyspnoea, during which the inspirations were observed to be short and frequent; the head was drawn back; the sense of suffocation appeared urgent; these attacks, which were protracted and severe, ended in a loud whoop or crow; between these, there was sometimes an interval of several days, and, during this period, the child appeared in tolerable health, but irritable and easily alarmed. After some time the paroxysms occurred more frequently, and began to excite, in the minds of the parents, considerable apprehension: the disease had been treated as a catarrhal affection. On my first visit the child was confined to bed, and laboured under well-marked symptoms of remitting fever; the pulse and respiration were accelerated, skin hot, tongue coated and florid at the edges, the papillae red and prominent, thirst, and the desire of cold drink urgent, the faeces thin and foetid; there was continual picking at the nose, and the diurnal exacer-

bations of fever were well marked; the veins of the head appeared unusually turgid; there were frequent attacks of spasmodic dyspnoea, such as have already been described; there was spastic contraction of the flexor muscles of the fingers and toes; the extremities were swollen, and of a slightly livid colour: this child suffered greatly from dentition, the teeth were unusually large, and were protruded at a very late period: on dividing the projecting and vascular gum of one of the molar teeth, some purulent matter was discharged. This child had had congenital cataracts; at the age of three months both eyes had been operated on; severe ophthalmia ensued: he had been copiously bled, and calomel had been given very largely; the child scarcely survived the treatment, and remained afterwards very feeble, emaciated, and delicate. A few leeches were now directed to be applied to the temples, calomel in minute doses was given every third or fourth hour, and occasional doses of castor oil; the febrile symptoms gradually subsided, the patient recovered slowly, and for some weeks remained without any return of the spasmodic attacks. After some time the child again began to suffer from difficult and painful dentition, and the spasmodic paroxysms recurred with violence; whilst in the act of dividing the gum, the spasmodic attack came on suddenly, and so urgently, that the face became livid, and there was complete opisthotonos; this spasm lasted so long, that respiration was for a time suspended, and for a few seconds I felt apprehensive lest the child should have died in the struggle. At length, after a long and sonorous inspiration, the spasm subsided, leaving the child in a weak and exhausted state. These formidable attacks recurred frequently, and were followed soon by general convulsions; it was now determined in consultation, that the child should be bled from the arm. The blood was allowed to flow until a perceptible effect was produced upon the system; for ten days afterwards there was not any return of convulsions or spasms; at the end of this time the paroxysms of dyspnoea, terminating sometimes in general convulsions, became again frequent. There now existed extreme emaciation, languor, complete anorexia; fingers and toes rigid; extremities purple and oedematous; nervousness; tremor; and starting at the slightest noises; under these circumstances an injection, consisting of five grains of tobacco-leaves in six ounces of water, was administered; the specific effects of tobacco, in a marked degree ensued, and it was remarkable that for a month afterwards no convulsive symptoms reappeared. About this period, a slighter recurrence of these symptoms led to the removal of the child from the city to the country, upon which they ceased immediately, and the child improved rapidly in health and strength; recovery appeared now so complete that the child was brought back to a large and newly-painted house in the city; when after a few hours the spasmodic attacks recurred with violence; on a second removal to the country, they ceased at once; a similar experiment was a second time tried, and with precisely similar results; and it is a curious fact, that two other children were attacked with a similar spasmodic affection in this same newly-painted house; of these, one died in a convulsion, the other, on being sent to the country, recovered; the child, whose case has just been related, had been for years free from any spasmodic affection, but remains delicate, and suffering severely from scrofulous disease.

This case exhibits the disease complicated with remitting fever, and with painful dentition; it also proves that the disease may exist to a most alarming extent, and yet recovery take place; the powerful effects of tobacco, in allaying spasmodic action, are also remarkably displayed. The importance of change of air as a remedy of prime efficacy in this affection, is strikingly exhibited. Nor is it undeserving of notice, that spasmodic disease seemed in two instances to be caused, and in this reproduced, by the contaminated air of a newly-painted house.

A child, nine months old, was brought to the Institution for the Diseases of Children, labouring under the spasmodic

* On the recovery of the child, this symptom gradually disappeared.

disease already described. This child had cut the four incisor teeth. Not having been at the time aware of this disease, I merely prescribed some medicine with the view of improving the digestive functions; there was no indication to lead to the conclusion that the child suffered from dentition. Some days afterwards, being sent for to see this patient, I found it violently and generally convulsed; the convulsive paroxysms succeeded each other at short intervals of time, and in about twenty-four hours proved fatal.

The body having been examined twenty-six hours after death, no morbid appearance was discoverable either in the abdominal or thoracic viscera; the mucous membrane of the larynx, trachea, and bronchi, exhibited a perfectly natural appearance; a very large quantity of fluid was found to have been accumulated in the ventricles of the brain; no morbid change had taken place in the brain; this was the only instance in which the disease under my observation, had terminated in hydrocephalus.

The following case was communicated to me by Dr. Johnson, Professor of Midwifery to the Royal College of Surgeons in Ireland:—

"I was consulted some time ago, about the child of the Hon. Mrs. P., and received the following history of the case:

"He was attacked on the third day after birth with laryngeal spasm and a crowing inspiration, in such a degree as to excite great apprehension in the minds of the parents; these attacks returned at intervals, when the child was irritated, and on awaking from sleep, until the third month, when they disappeared without any apparent cause. Between the fifth and sixth months they returned, accompanied by the swelling of the hands and feet, and the rigidity of the thumbs and toes described by Dr. Kellie (in *The Edinburgh Medical Journal*), and terminated in general convulsions. At this period he cut two incisors in the lower jaw; the attack of crowing inspiration returned frequently during dentition, sometimes alone, at other times accompanied by the rigidity of the thumbs and toes, but never terminating in convulsions, until he was cutting the first molar tooth. At the time that I was called to see him, the rigidity of the toes was so great as to prevent him from walking, and the screaming such as to render the parents apprehensive of the return of convulsions. On examination of the gums, I found the canine teeth making their appearance; the gums were divided, an issue inserted in the back of the neck, and aperient medicines were given. The attacks, however, were neither diminished in frequency nor violence, until the child was removed to the country, since which time he has had no return of the disease. He was a remarkably large and strong child for his age, which left the impression on my mind that he was over-fed; however, on inquiry I found this was not the case."

This case is interesting, inasmuch as it proves that this disease is not necessarily connected with the process of dentition,* although unquestionably exasperated in its symptoms, when the teeth are cut with pain or irritation; this case too, as the others, evinces the great value of change of air in the treatment.

I am indebted for the following interesting case to Mr. Newton, Licentiate of the College of Surgeons in Ireland, upon whose soundness and accuracy of observation the fullest reliance may be placed:—

"A child, aged nineteen months, of a violent temper, had always been very healthy until it was about seventeen months old, when he had a mild attack of whooping-cough, since which he was observed to have occasional fits of difficulty of breathing on awaking from sleep, during which his face became livid; these lasted for some time and were terminated by a long deep-drawn inspiration, with a crowing noise; this did not excite any alarm in his friends.

* Doctor Johnson has mentioned to me a case of this disease, the symptoms of which did not appear until after the teeth had been all cut.

"On the morning of the day on which he died, he took a hearty breakfast of stirabout, and in about an hour afterwards, he vomited; he was in good spirits and apparent good health until 5 P.M., when he was put into a passion; his breathing suddenly became difficult, his face livid, and he expired in about five minutes.

"DISSECTION SEVENTEEN HOURS AFTER DEATH.

"Extremities stiff, body fat, some lividity about scrotum and posterior parts of the body.

"On removing the skull cap, a large quantity of dark coloured fluid blood escaped; there was great turgescence of the vessels of the membranes of the brain. The brain was healthy; on removing it, a considerable quantity of blood escaped from the spinal canal.

"*Mouth and Throat.*—Uvula somewhat elongated, tonsils slightly enlarged. The rima glottidis was very much contracted. In the larynx, upper portion of the trachea, and in the œsophagus, numerous small portions of undigested oatmeal were observed; the mucous membrane of the air tubes presented everywhere a natural appearance. The lungs and right side of the heart were engorged with dark coloured blood. The mucous membrane of the stomach, about the pylorus, was softened and eroded. The muciparous glands of the small intestines were enlarged. No other disease was observed in any part of the body. On examining the larynx on the following day, the rima glottidis was found to have recovered its natural dimensions."

It is clear in this case, that the spasmodic closure of the rima glottidis was the immediate cause of death, no morbid change sufficient to account for death having taken place in any of the viscera. The turgid state of the vessels of the brain and lungs, as well as the gorged state of the heart, were evidently the effects of the suffocative struggle, and resulted altogether from the manner in which death took place. The symptoms at the commencement are thus proved to be purely spasmodic, and it is only when the disease increases in severity, and when general convulsions arise, that the brain, or its membranes, becomes the seat of disease. It would be interesting, on any future occasion, to examine accurately the state of the pneumogastric nerve. The seat of the disease may perhaps be found to exist at the *origin* of this nerve, and topical applications, made as nearly as possible to its origin, may be found to constitute an important part of the treatment.*

It seems to me not unimportant to remark, that all the cases of this disease, which I have witnessed, have occurred in children either themselves exhibiting marks of the strumous diathesis, or sprung from serofulous parents. This bears practically upon the subject, inasmuch as it enhances the value, in treatment, of pure air, healthy nutriment, and tonic remedies.

If we take a survey of the several cases of this disease, which have been stated, we learn that it varies much in degree, and that its complications are numerous. In its mildest and least complicated form, the spasmodic action is confined to the muscles of the glottis, and the treatment consists in improving the general health, and in giving tone to the nervous system. The symptoms in such cases will rarely fail to yield to some of the vegetable or mineral tonics, pure and bracing air, and a well regulated diet; in some cases I have perceived, I think, advantage to arise from some of the antispasmodic medicines, and amongst these none has appeared to me more beneficial than the old-fashioned medicine, the *tinctura fuliginis*; but when

* Dr. Monro, in his work on the "Morbid Anatomy of the Brain," describes a variety of acute hydrocephalus ushered in with spasmodic symptoms affecting the muscles of the glottis, and in one case, describing the morbid appearances, he says—"All the nerves, at their origin, were sound, except the fifth and eighth pairs, which were also of a deep scarlet colour and covered with turgid vessels. On removing the brain, by cutting through the medulla oblongata, a considerable quantity of serum rushed from the upper part of the spinal canal. The vessels of the spinal marrow were turgid, those at the cervical portion of a vermilion red colour, and those of the lumbar portion of a dark red hue. The eighth pair of nerves were of deep uniform red along its whole tract, as far as its branches going to the lungs."

the disease is complicated with painful dentition, derangement of the bowels, or any febrile movement in the system, the primary object of the treatment must be, to remove these accompanying ailments; until this be effected the treatment applicable to the spasmodic affection, though it may mitigate its severity, will fail to eradicate the disease. When the spasmodic symptoms extend themselves, and implicate the muscles of the extremities, the disease assumes a more formidable aspect, and soon, if not checked in its progress, paroxysms of general convulsions will establish themselves. In this stage the membranes of the brain become so frequently engaged, that the utmost vigilance on the part of the practitioner is required to prevent the occurrence of such mischief; yet it must not be lost sight of that the disease, even in its mildest form, is attended with danger. One case is recorded of sudden death during the spasmodic closure of the glottis; this occurred in a child who was otherwise in perfect health, and I have heard of several instances of the same kind. In every stage of the disease, therefore, we should be aware of and guard against the liability to sudden death; all needless sources of irritation should be avoided, and the child closely watched, and carefully held and supported during the paroxysm of dyspnoea. In irritable and passionate children the danger is increased. Dr. Johnson has stated to me, that he has seen a child, in a state of asphyxia caused by this disease, recovered from apparent death by the instantaneous application of artificial respiration.

Dr. Cheyne, in his treatise on hydrocephalus,* gives a very just delineation of this affection; he describes it as consisting in a crowing inspiration with purple complexion, *not followed by cough*; he mentions the rigidity of the muscles, the thumbs clenched in the hands, the peculiar livid and swollen appearance of the extremities, and the occurrence of universal convulsions; he states that seven instances, to his own knowledge, have ended in death; and in regard to treatment, he has dwelt with peculiar emphasis upon the importance of change of air and change of diet, as the means of greatest efficacy in effecting a permanent removal of the disease.

Dr. George Kellie of Leith, has published a short paper,† entitled, "Notes on the Swelling of the Tops of the Hands and Feet, and on a Spasmodic Affection of the Thumbs and Toes, which very commonly attends it." This condition of the extremities he has described very accurately, and the reader will do well to pursue his paper with attention; it must, however, be remarked, that this symptom belongs to a more advanced stage of the disease, and does not exist until either the general health be considerably impaired, or the spasmodic symptoms have increased in frequency and severity; it is therefore not essential to the disease.

Mr. Porter, in his valuable observations on the surgical pathology of the larynx and trachea, alludes to this disease, and particularly mentions the fact, that it occasionally happens that the child, during the convulsion, dies before assistance can be procured.

In *The London Medical and Physical Journal*, vol. xlv., p. 9, this disease is spoken of by W. Pretty, Esq., under the name of cerebral croup, a denomination which is objectionable, because it is more than doubtful, whether in this affection, at its commencement, the brain be at all involved; and secondly, because in its symptoms and progress it is altogether distinct from croup. He describes with accuracy the symptoms in three of his own children; of these, one died, the others recovered. In speaking of the treatment of one of those cases he concludes with the following words:—"The spasms frequently recurring, his nurse was changed, and he was sent to the country; he is now a fine healthy little fellow." He justly dwells upon the importance of attending to the state of the head during the entire progress of the disease, and also upon the necessity of

dividing the gums whenever the process of dentition may appear to be a source of irritation.

In the fifth volume of Richter's "Specielle Therapie," there is a tolerably accurate account of this spasmodic affection.

The facts which have been recorded, and the references which have been made, prove that this disease is of more frequent occurrence than has generally been supposed.

A controversy has been maintained for a long time, as to the existence or non-existence of spasmodic croup—a disease which I believe to be nothing else than the first stage of inflammatory croup, or else a slight and transient attack of croup in nervous and irritable children. The disease which forms the subject of this paper is essentially different from every form and variety of croup; it is a purely spasmodic affection, and in all its stages is characterized by convulsive movements, partial or universal, and in its earlier stages all its symptoms will be aggravated if it be confounded, in treatment, with any inflammatory affection of the larynx or air tubes. This mistake has been often made; it therefore seems to me important to distinguish this disease from other affections with which it has been often confounded and to set forth the principles of treatment which are directly founded on this diagnosis. I may also mention, as an additional reason for dwelling on the characteristic features of this affection, that I do not find it described in any systematic work in the English or French languages.

(To be continued.)

TRISMUS, RUNNING INTO GENERAL CONVULSIONS, OCCURRING IN A CHILD AT BIRTH.

By G. de GORREQUER GRIFFITH,

PHYSICIAN TO THE HOSPITAL FOR WOMEN AND CHILDREN, PIMLICO;
PHYSICIAN-ACCOCHEUR TO ST. SAUVOUR'S MATERNITY; AND SOME TIME
RESIDENT SURGEON AT THE HOME FOR DISEASES OF WOMEN, &c., &c.

RECENTLY I was called to attend Mrs. H—, in her first labour. She is a low-sized woman, small-built, and about 29 years of age.

On examination I found the os open to the size of a florin; its edge was thin, firm and undilatable; the pains were not strong, but the patient forced voluntarily a good deal, so as to lead to the supposition that the strong bearing-down muscular action which she used was severe expulsive labour pain.

As there was inertia of the womb, and very little (after the womb had opened fully) had been effected by the feeble uterine action during the interval of some hours, I ordered her a dose of ergot, and begged of her to desist from her forcing down, since it in no way helped her, but, on the contrary, delayed her delivery by exhausting her strength.

I should mention that in the course of examination I found the pelvis in all its measurements smaller than usual, though there was no actual deformity; the antero-posterior measurement was the most narrowed. In addition, there had been, in the commencement of labour, great rigidity of the os, and of the soft parts, and I had prepared my patient for a slow and somewhat tedious "time." After the exhibition of the ergot true uterine action set in; but still so feebly that it was only sufficient to cause the descent of the head by very slow degrees; moreover, the narrowing of the antero-posterior diameter delayed the birth still further, the head of the child adapting itself but slowly to the diminution in the calibre of the pelvis.

As the labour was progressing slowly but favourably as concerned the mother, I did not think it wise to interfere.

The baby was born in that half-lifeless state which obtains when labour is very tedious, and the child's head is greatly compressed, specially from the forehead to the occiput, as in this instance. The amount of compression was so great that there was literally no forehead—the

* Second Edition, page 16.

† *Edinburgh Medical and Surgical Journal*, October, 1816.

top of the head beginning immediately at the eyebrows, and running very far upwards and backwards in the form of a cone.

With much difficulty, and after prolonged efforts, the child was made to take hold, as it were, of existence; but as soon as life was established, I perceived that the lower jaw, though slightly depressed, was firmly locked, and could be forced open only by some little effort.

The head was drawn backwards, and the muscles of the neck were rigidly contracted; the arms, fore-arms, and hands next became engaged in the convulsions, which subsequently became general, a condition of opisthotonos prevailing.

On the next day the child had fallen into a state of coma, which supervened in death during the same day.

Antero-posterior compression, more particularly to such an extent as occurred in this case, is so hazardous to infant life, and so commonly fatal, that I shall do no more than allude to it in order to call attention to the fact; but that it occasions trismus and general convulsions is not, I believe, so well established. Trismus is, in itself, a rare affection in children; but as a result of compression of the head during birth, is still more rare.

2, Lupus-street, Pimlico, London, S.W.

ON THE TREATMENT AND PREVENTION OF CHOLERA.

By W. JACKSON CUMMINS, M.D.,

PHYSICIAN TO THE CORK DISPENSARY AND BLACKROCK CHOLERA DISTRICT.

To Professor Polli of Milan, and Dr. De Ricci of Dublin, the profession are indebted for the knowledge that sulphuric acid administered internally in the form of bisulphites arrests fermentation and thus stays the progress of zymotic disease. In a paper which I published on scarlatina in the 39th vol. of "The Dublin Quarterly," are a number of cases in which the bisulphite of soda produced beneficial effects, and used as a prophylactic prevented the spread of the disease. Since then I have had few opportunities of experimenting further with the medicine, as scarlatina has not prevailed epidemically, but in one most malignant case which occurred I used it successfully, and also prevented the spread of disease among the other children in the house. I also used it as a prophylactic for diphtheria with success. Dr. Hayden of Dublin, has also found it beneficial in the latter disease.

Although Dr. de Ricci, in his last paper ("Quarterly," November, 1866), prefers the sulphite of magnesia to the salt of soda, I still prefer the latter, its greater solubility making it more easy of administration. It has surprised me that some observers have stated that bisulphite of soda causes troublesome diarrhoea, as I never found it produce such effect, or indeed any manifest effect, even in large doses. Its slightly smoky taste is not disagreeable, and children take readily a solution of a drachm in half a pint of water, from half a glass to a glass three or four times a day, or even much oftener, when actually suffering from disease. But since the appearance of cholera in Cork I have used sulphuric acid in a different, and I believe much more efficacious manner—viz., by inhalation. In a concentrated form the acid is of course poisonous, but when largely diluted by the atmosphere, it is neither noxious nor very disagreeable. My mode of proceeding is to take a shovelful of live coal out of the fire and place it in the centre of the apartment, then to sprinkle on it a small quantity of sulphur, which burns with a blue flame, setting free the acid, which permeates every part of the room. The quantity to be used must depend on the size of the room, but by commencing with a little it will be readily found out how much can be borne without discomfort. As soon as the smell has nearly passed away, a little more sulphur may be sprinkled as before, and renewed cautiously from time to time. If by burning accident-

ally too much at a time the patient or attendants are made cough or sneeze, a window may be opened to renew the air; and I can say that I never have found any bad consequences follow even where proper caution has not been used.

As a disinfectant after death, I know nothing equal to sulphuric acid. I shut all doors and windows and throw a large quantity of sulphur on the coals placed as before. The room becomes presently intolerable, but on re-entering it after an hour or two it is perfectly pure, and free from smell. I was a strong non-contagionist regarding cholera (as I believe most people were), when former epidemics prevailed, but I have seen enough during the present to make me believe it at least portable, and I think we cannot guard too much against its spread through the discharges, through the atmosphere, or from individual to individual; although it is by no means proved that the disease can be communicated in the last of these ways.

The effect of sulphuric acid on the cholera patient and his attendants is most useful—curative to the former and prophylactic to the latter. I have seen cases recover which I considered well nigh hopeless, while all the fatal cases, three in number, occurred before I had commenced using it, so that I attribute the success in great measure to the use of the acid. In these days, when every one is writing his opinion and treatment of cholera, one does not like to obtrude his notions when his experience has been comparatively limited, yet, as I am on the subject, I shall briefly note my ideas of its pathology, and the treatment I adopt. No one who has seen cholera and watched closely its phenomena can doubt for a moment that circulation is almost completely arrested, that the veins are full to distension, and that the arteries are almost, if not entirely empty. The natural inference is, that there is an obstruction in the capillaries. Opinion is divided between two theories as to the cause of this—viz., 1st, that in consequence of the serous drain, the blood is too thick to pass through those little vessels (the old view); and 2nd, that in consequence of a tetanic spasm of the capillaries, the blood cannot pass from the right side of the heart and veins, being arrested in the capillaries of the lungs on one side, and of the system generally on the other, so that the discharges are an effect, not a cause (the new view, so well worked out by Drs. Johnson and Bell). Without entering into the evidence for and against those theories, I may say that I think symptoms and morbid pathology favour the latter, and that there is at least one insurmountable objection to the former—viz., that collapse is more intense when at its acme than it is when the patient is beginning to recover, although meantime there has been a large out-pouring of fluid.

Without believing that preliminary diarrhoea in itself can cause collapse through draining away the serum of the blood, my observation certainly leads me to the belief that gastric or gastro-enteric irritation may be the starting point of the symptoms of cholera; there must be, however, a preceding operation of the cholera poison on the constitution, predisposing it to the specific effect which a gastro-enteric irritant can produce, in cholera times alone.

I have seen cholera follow almost immediately upon taking an indigestible meal in some cases, one more especially—a most instructive case in many ways—a boy, æt. 10, residing in the house with his sister, who was passing through secondary fever after cholera, was quite well until the afternoon of the day he was attacked, when he ate some raw turnips; at six o'clock vomiting and purging commenced; at nine, when I saw him, he was in collapse; at eleven he was pulseless and hopeless; the venous system engorged almost to blackness; conjunctiva congested to such an extent that black blood exuded from its vessels during the agony, and he died in a few hours. This case was struck down from the first; nothing could have saved him.

In the condition of system superinduced by the poison

imbibed from his sister, or her discharges, the gastric irritant instead of setting up an ordinary vomiting and purging for its removal from the *prima via*, transmitted its irritation to the ganglionic nervous centres, and by reflex action caused that crampy contraction of the muscles of the capillaries, which prevented the blood from passing freely into the arteries; serum was poured out from the veins to relieve their distention, while at the same time, from arrested pulmonary circulation, the interchange of gases between the blood and the air was imperfect; the blood was not decarbonised, animal heat was not renewed, excretion was arrested from want of oxygen, as well as from venous congestion of the glands, and the patient sank from absolute arrest of circulation.

I am not going to enter into the details which bear out this view of the pathology of cholera. Dr. Johnson's book is replete with them. I only allude to it in order to point out the indications for treatment, which I endeavour to fulfil in the following manner:

1st. By burning sulphur as aforesaid, to arrest the zymotic action, which, I believe, forms the cholera constitution.

2nd. Endeavouring to relieve gastric or gastro-enteric irritation, by giving from twenty to forty drops of laudanum, and from twenty to thirty drops of chlorodyne in a little cold water, repeating it according to circumstances.

3rd. Giving ten drops of a saturated solution of camphor in chloroform every half hour or hour, in a spoonful of sugar, arrow-root, or gruel, to relieve spasm or cramp.

4th. Endeavouring to maintain heat by the ordinary means, and fomenting the patient with hot water and turpentine or mustard.

5th. Economising the vital powers by rest.

6th. Supporting strength by cold milk, and soda water with a little brandy.

7th. Giving ice internally for its effect on the semi-lunar ganglion and solar plexus, if able to obtain it.

8th. Except indirectly, by means of sedatives and antispasmodics, I should object to arresting serous discharges; direct astringents I should think most objectionable.

CONTRIBUTIONS TO THE PATHOLOGY AND TREATMENT OF CHOLERA

SOME CASES SUCCESSFULLY TREATED ON THE DIURETIC PLAN.

By AUSTIN MELDON, L.K.Q.C.P., L.R.C.S.I., L.M.,
ASSISTANT MEDICAL OFFICER TO GRAND CANAL-STREET DISPENSARY, &c.

WILLIAM MURRAY, aged 11 years, had been suffering from diarrhoea for some days previous to Saturday, the 3rd November, on which night he awoke suffering from intense pain in the abdomen, great sense of exhaustion, copious diarrhoea, and vomiting. I was summoned to attend at two A.M., and found the child with well marked cholera and fast sinking into collapse; pulse was almost imperceptible; breath cold; voice low, whispering, and unnatural; skin cold and clammy; severe cramps in the thighs; insatiable thirst; suppression of urine; the liquid rice-water stools being passed freely all about the bed; no urine had been voided during the entire day; I endeavoured in vain to persuade his parents to send him to hospital; I therefore proceeded to treat him as follows:—A large poultice, made with two parts of linseed-meal to one of mustard, was put over the abdomen, and the following ordered:—

℞ Plumbi acetatis, gr. xxiv.
Acidi acetici, ℥ij.
Morphiæ acetatis, gr. i.
Spiritus ætheris nitrosi, ℥iv.
Spiritus juniperi, ℥i.
Aquæ camphoræ ad. ℥viiij. M.

A dessertspoonful of this mixture every half hour.

November 4th, eight A.M. Vomiting and purging somewhat less; he passed a little urine this morning; seems a little more lively; pulse as yet but feeble; skin warm, and there is slight perspiration; cramps completely disappeared.

Five o'clock P.M. Skin quite warm and perspiring; passed urine freely two or three times during the day; pulse pretty strong, and seems in every way much improved.

6th, twelve A.M. Little vomiting and no purging; urine passed freely; pulse strong, and he is in every way progressing.

7th. Vomiting and diarrhoea have returned; urine became scanty. The mist. plumbi acetat. et junip. having been discontinued on the previous day, I ordered it to be recommenced.

Four P.M. Free discharge of urine; purging stopped; vomiting not so bad as in the morning.

8th. No purging, but slight vomiting; urine passed freely.

9th. No vomiting or purging.

10th. Convalescent.

I was summoned to attend M. Ellis, Clarence-street, on the night of the 3rd instant, and found her in a state of nearly complete collapse; the vox cholericæ was well marked; vomiting and purging had been present during the entire day; no urine had been secreted for some time previous; there was great pain in the abdominal region; the cramps were very severe and frequent; pulse very weak; skin cold and of a livid colour. The mother refusing to send the child to hospital, I ordered a dessertspoonful of the mistura acetat. plumbi et junip. every half hour.

4th. Heat returned to the surface; cramps less severe; vomiting and purging less than on the previous day; pulse stronger; urine secreted; ordered to continue the treatment.

5th. Purging almost ceased; vomiting continues; urine secreted freely; cramps completely ceased; little pain in the abdomen.

6th. Much improved in every way; vomiting almost ceased.

7th. Seems convalescent.

(Four P.M.) Vomiting has returned, and slight diarrhoea set in; ordered to recommence the mixture.

8th. Vomiting less, and purging ceased; convalescent.

Michael Boylan, 100, Townsend-street, aged 40 years, was attacked on the 3rd of November with violent vomiting and purging, together with severe pain in the abdominal region; he had been previously suffering from diarrhoea for two or three days. The stools were at first natural, but after a little became like rice and water. I saw him about an hour after the first attack. He had slight cramps; passed very little urine during the day. I ordered him to take two tablespoonfuls of mist. acetat. plumbi et junip. every second hour.

I called again in about three hours, and found there had been a large secretion of urine, after which the vomiting and diarrhoea had ceased, and he now seemed quite well. He has not since had a relapse.

A. B., 16, Moss-street, was suffering from well-marked cholera, and had been treated on the previous day with acetat. plumbi et opii; he was very weak, and verging on collapse, little urine being passed for some days previously. Ordered mist. plumbi acetatis et junip.

4th. From this date he continued to improve, until the 7th, when he was pronounced convalescent.

James Gavan, 6, Clarence-street, sent to the dispensary for relief at two A.M. on the night of Thursday the 15th. On my arrival I found him verging on collapse; his skin was quite dusky and cold; no urine had been secreted for some time past; the eyes were considerably sunken; cramps very severe and the vox cholericæ was well marked; the lower part of the abdomen was swollen and painful, he had been vomiting and purging during the entire night; the pulse was imperceptible. Ordered two tablespoonfuls of the mist. acetat. plumbi et junip. every second hour.

Friday, eight A.M. Pulse perceptible at the wrist; skin warm, perspiring a little; urine passed; the other symptoms continue unabated.

One P.M. Pulse stronger; kidneys acting; purging less; vomiting only when he takes something.

Six P.M. Continues to improve.

Saturday, eight A.M. Purging ceased; vomiting less; kidneys acting well; pulse stronger; skin resumed its natural colour, and in fact he seems on the way towards recovery.

Sunday. Considerably improved in every way; seems convalescent.

Ten P.M. Became feverish, and was sent to hospital.

James Byrne, 7, Hanover-street, was attacked on Thursday night with severe vomiting and purging, accompanied by cramps; little urine had been secreted during the day previous; ordered the mist. acetat plumbi et junip.

Friday, eight A.M. The symptoms somewhat abated in severity; urine passed, and from this time until Sunday, 18th, all the symptoms ceased, except slight diarrhoea, in which, however, the stools were of the natural colour, and which was arrested by large doses of opium; in every other way he was on this date quite well.

29, Westland-row.

Hospital Reports.

SPECIAL REPORT

ON THE

TREATMENT OF CHOLERA

BY VENOUS INJECTIONS.

IV.

THE EPIDEMIC OF 1848-9.

(Continued from page 509.)

WE have now placed upon record a number of cases treated by this method in the epidemics of 1832 and 1849, and as in that of 1854 the hospitals of London did not admit cholera patients, we are in a position to sum up our knowledge of the subject, prior to the recent outbreak, which will form a subsequent section of this report.

Without attempting to reduce the conclusions to a few dogmatic assertions, and with no intention of entering minutely into the whole pathology of this disease, we may possibly sufficiently formulate some of the lessons to be derived from experience up to this date, to serve as a practical compendium and guide. We can scarcely do wrong in starting with the generally accepted fact that one of the most serious items of cholera is the enormous drain upon the fluids, and the difficulty of furnishing a fresh supply from the complete interruption of the function of absorption. Thus it is that we so commonly find that after death the stomach is full of water, which has been administered during life, without appeasing the insatiable craving of the patient for drink. It has been thought by some that fluids might be supplied through the skin, but packing in wet sheets has failed as signally as prolonged baths to render the cutaneous surface supple and stimulate it to absorption. Clearly, then, injection of liquids into the veins affords a means of supplying this want of fluid.

Further, as the saline propensities of the blood pass away with the fluids, it is equally natural to attempt to supply this loss by adding certain salts to the injection. We may, indeed, feel considerable hesitation as to the exact specific gravity of the liquid most likely to furnish the best substitute for the lost fluid, since this property could scarcely fail to exercise the ordinary physical effects on the blood globules; yet it is not to be denied

that these corpuscles in a patient whose blood has been drained of liquid and salts are already in a changed state, the only possibility of restoring them being a plentiful supply of water, and perhaps of saline particles also. Injection into the veins enables us to place the requisite materials in immediate contact with the blood corpuscles; so that we might *a priori* anticipate that by this treatment the thick dark blood, so familiar to the pathologist after death from cholera, might be changed to a more normal condition. That this anticipation has been realized is shown in an observation of Drs. Letheby and Little, who, at a post-mortem on a patient who died after venous injections, found the blood to all appearance quite healthy. In this case, in which 100 ounces of fluid had been injected two and a half hours before death, the venæ cavæ, pulmonary veins, and cavities of the heart, were filled with *bright coloured* coagulated blood—a condition that may fairly be attributed to the effect of the injection. Whence otherwise the natural hue and coagulability of the blood?

We may, then, take it for granted that fluids and salines may in certain conditions of the system, such as those met with in the collapse stage of cholera, and of course with due precautions, be introduced into the circulation with comparative safety, and often perhaps with benefit. The addition of alcohol was not unreasonable, as it might be fairly expected to retard the relapse. At any rate, it offered a certain means of administering a stimulant, and was a substance not incompatible with the life of the blood. The cases we have recorded would seem to show that these hopes were well founded.

The earlier accounts of the effects of this operation can scarcely be said to have been exaggerated. This remedy is probably the most powerful known stimulant to the circulatory as well as to the nervous system. The injection at once restores the circulation and the respiration. As soon as the blood becomes mixed with the warm injection the pulse is restored, and the countenance assumes a more natural hue. The fearful oppression, which torments so many, passes off, colour and warmth gradually return to the whole surface, perspiration breaks out, the voice is regained, and from a hopeless state of collapse, from a condition almost of death, the patient may sit up and converse without distress. It has been several times remarked to the writer by eye-witnesses of the cases, that any one apparently dead might thus be enabled to make his will.

It will have been remarked that sudden and copious vomiting or purging has sometimes returned after this amendment, as if the patient had only been removed from the collapsed back to the prior stage. In Case 8 this was twice followed by renewed collapse, each time again relieved by injection.

It would thus appear as if not only could life be maintained for a certain time by venous injections, but the system restored to such a condition as to give an opportunity of supplying other remedial agents; and, perhaps, more important still, of taking some sort of nutriment. When the relief obtained has been permanent, the urine has reappeared, and the renewal of this function constitutes the most hopeful element in the prognosis. An agent which had apparently restored two such important secretions as those of the skin and kidneys, and that when nothing could be introduced into the system through the mucous membranes, deserved a further trial, and this, as we shall see hereafter, it has had in the present year.

The cases already related in our report demonstrate that the danger attendant on this operation is not so great as has been supposed—a conclusion which we anticipate will be abundantly corroborated by the cases treated in the present epidemic, which we shall next analyse. As to the proportion of recoveries, we must remember how small this has been under every method of treatment yet tried in the stage of collapse.

MATER MISERICORDIÆ HOSPITAL.

TWO CASES OF PERITONEAL
PNEUMATOSIS.

(Under the care of Dr. HAYDEN.)

Case 1.—M. C., aged 44, by occupation a laundress, presented herself amongst the extern patients of the hospital, on the 10th October last, to seek advice regarding a certain enlargement of the abdomen which had existed for the last three years.

The patient was anæmic, with a slight olive tint of face, and a somewhat hysterical look; had nine living children, and three miscarriages; on the occasion of the last miscarriage, which occurred three years ago, she lost a good deal of blood by flooding, and immediately afterwards the abdominal enlargement set in, and has continued with little variation up to the present date.

Pulse 90 and regular, as is likewise action of heart; the abdomen is globular in shape, tympanitic and tense, and of the size presented in the last month of pregnancy; bowels regular; menses have not appeared for the last three months.

℞ Pil. Alæ. c.

— fœtid c. aa. gr. ii.

Extract. nucis vomicæ, gr. ss.

M. Et ft. pil. habeat xii. tales, et st. i. ter indies.

October 24th: This patient presented herself at the hospital dispensary to-day; abdomen softer, but still large and tympanitic.

On the 12th of November she was admitted under my colleague Dr. Hughes, and whilst doing temporary duty for him I had the opportunity of observing and treating her in hospital; since that date she has been taking, three times daily, ten drops of liquor of the pernitrate of iron in infusion of calumba; the abdomen is now (November 21st) soft and comparatively lax, but still large and tympanitic.

Case 2.—Ellen H., aged 52, dress-maker, never married, admitted into hospital October 15, 1866; had enjoyed good health till six months previous to the date of admittance; about that time she began to complain of pain in the right side of the abdomen and in the right shoulder; she became weak and thin, and her appetite failed. About the 1st of September last she began to suffer from spasmodic pain in the abdomen; the attacks came on when she was at rest, and now the abdomen became rapidly enlarged, and attained to its present dimensions in the course of a few days.

At date of admittance pulse was quick and feeble; there was total loss of appetite, and irritability of stomach; bowels regular; patient was unable to lie down with enjoyment owing to a sense of distension and dyspnœa, which immediately ensued on her assuming the recumbent posture. The abdomen was globular, greatly enlarged, tense and tympanitic at all points. About three days after admission the feet and legs became swollen, and diarrhœa set in. Liquor of the pernitrate of iron was given in ten-drop doses in infusion of calumba, and four ounces of wine daily, with nutritious diet.

About a week since (14th Nov.) the abdominal enlargement began gradually to subside, and at the present date (Nov. 21st), it has entirely disappeared; pulse is now 108, and moderately good in volume; tongue clean; appetite better; bowels regular; and patient's strength so much improved that she can sit up for the entire day and walk occasionally about the ward; the feet and legs are no longer œdematous, and the patient, though still weak, contemplates leaving hospital in the course of a few days.

Coincidentally with the subsidence of the abdominal enlargement, a flat, rugged, and solid body became perceptible to the touch in the umbilical region; in its greatest diameter—which extends transversely to the left,

from the right margin of the umbilicus, it measures three inches, and in its vertical diameter about one inch and a half; it is not sensitive to pressure; yields a modified tympanitic sound on percussion, such a sound as might be elicited from a solid body—resting on a hollow and air-distended viscus; it recedes under the pressure of the fingers, and is surrounded at all points of its circumference by resonant surface.

Abdominal pneumatosis, especially the peritoneal form, is sometimes most obstinate to treatment. Of the latter form Dr. Graves (*Clinical Medicine*, vol. ii., page 77), says, "In this variety of the disease the general health is unimpaired; the appetite good; the bowels regular; and the patient does not complain of flatulence, borborygmi, or colicky pains; the shape of the belly, too, in peritoneal tympanitis, is more prominent and globular than in the intestinal, and in appearance more closely resembles the abdomen of a woman far advanced in pregnancy; the latter circumstance, indeed, often constitutes the sole annoyance complained of by the patients, who are generally young unmarried females."

Dr. Graves also speaks of the gradual growth of these enlargements as being characteristic, and also of their not being subject to temporary alterations in size. In acute cases, he observes, the prognosis is better, and the disease more easily cured; this tractable form occurs shortly after pregnancy.

The cases which I have detailed, it will be perceived, are exceptional in regard to many of the features laid down as characteristic by Dr. Graves. In the first case the inflation occurred rapidly, and after miscarriage; yet it has proved, up to a very recent date, obstinate to treatment, though now slowly yielding; and in the second case the general health is in an unsatisfactory state, but this may be in a great measure attributed to the co-existence of organic disease in the abdomen.

If any doubt had existed as to the precise situation of the œriform accumulation, it would have been removed by the detection of induration—I doubt not of the anterior wall of the stomach *only* after the subsidence of the tympanitic enlargement; had the site of the gas been the stomach or intestinal canal, the tumor must have been brought to the surface, assuming that it did not take its origin from the liver, an assumption warranted by the recession of the body under pressure, its situation, and the clearness on percussion of the surrounding surface; there is, moreover, no evidence whatever, either in the history or present condition of the patient, of enlargement or any form of disease of the liver.

The progress of both the cases has been so far satisfactory under a tonic and chalybeate treatment.

CHOLERA.

In the forty-sixth week of the year, which ended Saturday, November 17th, the total deaths registered in London were less by 91 than the estimated number. This is the second week in which the mortality has been below the average since the outbreak of cholera. This disease carried off 32 persons during the week, besides 22 deaths from diarrhœa, so that but for this form of disease the returns would present a most remarkably favourable state of the public health. The deaths from cholera during the last five weeks have been, successively, 144, 112, 73, 67, and 32. These figures represent a gradual decline. Nevertheless, it is important to note that both in 1849 and 1854 the decrease was much more rapid than in the epidemic. The outbreak at Woolwich and Charlton, which has kept up the figures lately, is, we are happy to say rapidly subsiding; and steps have been taken to secure better drainage. Since the weekly return was completed the decline has continued, so that we trust shortly to have

to report the total disappearance of the epidemic. On Tuesday the 20th only 1 death was registered from cholera and 4 deaths from diarrhoea, in all the London districts, containing a population of more than 300,000.

The annual rate of mortality during the week was 24 per 1000 in London, 28 in Edinburgh, and 37 in Dublin; 20 in Bristol, 20 in Birmingham, 29 in Liverpool, 30 in Manchester, 29 in Salford, 25 in Sheffield, 28 in Leeds, 19 in Hull, 37 in Newcastle-upon-Tyne, and 31 in Glasgow.

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29.693 in. The mean temperature of the air in the week was 45.6 deg., which is 2.4 deg. above the average of the same week in fifty years (as determined by Mr. Glaisher). The entire range of temperature in the week was 27.7 deg. The mean of the highest temperature of the water of the Thames was 48.5 deg.; that of the lowest was 46.5 deg. The difference between the mean dew-point temperature and air temperature was 5.4 deg. The mean degree of humidity of the air was 82, complete saturation being represented by 100. Rain fell during the week to the amount of 0.58 in. An extraordinary shower of very brilliant meteors occurred during the early morning hours of Wednesday; fully 10,000 meteors were seen at the Royal Observatory, Greenwich. According to a return furnished by the engineer of the Metropolitan Board of Works, the average daily quantity of sewage pumped into the river Thames at the southern outfall works, Crossness, was 197,542 metric tons.

A very important inquiry into the physical properties of "cholera stuff" has been conducted by Professor Frankland, who informs the Registrar-General that it passes through filtering paper, and that "water containing the 1-500th part of the matter, is not entirely purified by transmission through animal charcoal." Further, we learn on the same authority, that it has not yet been decided "whether the properties of the remaining molecules or organism undergo any change in the filtering process, depriving them of their zymotic character."

The conclusion to be drawn from these statements can only enforce the necessity of destroying, as far as possible, all excretion, and doubling our precautions against the contamination of the water supply.

EDINBURGH.

During the same week 11 cases had been admitted to the hospital in Edinburgh, besides two patients treated in their own houses. There were 6 deaths, of which 5 were in the hospital. There were 5 deaths in 10 days in Leith. At the small village of Leven, where 50 fatal cases had occurred, including, as we named last week, Dr. Kennedy, we hear Dr. Balfour had gone to attend to the poor. Eight wells were reported by Drs. Stevenson and Macadam to be contaminated with sewage. Since they have been closed the epidemic has rapidly declined. We have also to report 10 deaths in 4 days at Buckhaven; 5 or 6 per diem at Methil, and several at Lochee, near Dundee.

PROFESSOR FRANKLAND ON THE RICE-WATER EVACUATIONS OF CHOLERA PATIENTS.

As mentioned in another column, a very interesting report has been made to the Registrar-General, on cholera ex-

creta, by Professor Frankland, F.R.S., of the Royal College of Chemistry. Investigation, of this nature, undertaken by reliable authorities, are so rare, and the opportunity of continuing such experiments is, happily, so rapidly passing by, that we feel it a duty to lay before our readers the results arrived at. Dr. Frankland's report is so complete in itself, and at the same time so brief, that we have no hesitation in printing it *in extenso*, merely premising that the matter experimented on was taken from a patient who died of cholera in the temporary hospital in Commercial-street:—

"10th November, 1866.

"On the 27th ult. I received from Dr. Farr three bottles containing the rice-water evacuations of a cholera patient collected on the previous day.* After agitation the rice-water had the appearance of thin cream, from which a small amount of flocculent matter gradually subsided after the lapse of some hours, leaving a supernatant liquid looking exactly like milk, and from which no further perceptible subsidence took place, even after the lapse of several days.

"One volume of this choleraic evacuation was mixed with ten parts of distilled water, and sealed up in a long glass tube; the flocculent matter now subsided much more readily, leaving an opalescent liquid above. One volume of the rice-water was mixed with 100 volumes of distilled water, and sealed up in a similar glass tube. The flocculent precipitate now subsided more readily.

"One volume of the rice-water was mixed with 500 volumes of distilled water, and the mixture passed through filter paper. The filtered liquid was still very opalescent, proving that a process of filtration, far more perfect than any available for the filtration of water upon a large scale, fails to remove entirely the suspended matter of choleraic evacuations.

"Submitted to the action of potassic permanganate, 100,000 parts of the filtered liquid just mentioned required .0430 part of oxygen for the oxidation of the organic matter contained in it. The average amount of oxygen required to oxidise the organic matter contained in 100,000 parts of filtered Thames water as supplied to the metropolis is .0721 part. Thus a sample of water containing 1-500th of its volume of choleraic evacuation exhibits, when tested by potassic permanganate, a much greater degree of purity as regards organic matter than the water supplied to the inhabitants of the metropolis; in fact it may be safely asserted that the addition of cholera rice-water to the water of the Thames in the proportion of 1 to 1000 would not materially affect the results of a chemical analysis of the water.

"After rapidly passing the above filtered but opalescent liquid (containing 1-500th of choleraic evacuation) through animal charcoal, the opalescence was diminished, but not entirely removed. The organic matter still remaining in 100,000 parts of it now required only .0103 part of oxygen for its oxidation. Animal charcoal therefore fails to remove entirely, even from previously filtered water, the suspended matter of choleraic evacuations.

"The foregoing experiments show (first) that water may become seriously contaminated with choleraic matter without the presence of the latter being indicated by chemical analysis, and (secondly) that water so contaminated is not completely deprived of this impurity either by filtration or passage through animal charcoal.

"It still remains to be proved to what particular constituent of choleraic dejections the propagation of the disease is due, but it is obvious that if the propagating matter be a germ or an organism it must be in suspension and not in solution.—I have, &c.,

"E. FRANKLAND."

* The cholera matter was supplied by Dr. Sutton, Pathologist to the London Hospital.

Proceedings of Societies.

HARVEIAN SOCIETY OF LONDON.

November 1st, 1866.

Dr. THOMAS BALLARD, V.P., in the Chair.

DR. THOMAS BALLARD read a paper

ON EPISTAXIS AND ITS TREATMENT; WITH CASES.

An opinion is generally prevalent that epistaxis in young persons is of little importance, and never attended with danger, and in the case of adults, that the bleeding is salutary, and relief to an overloaded vascular system, that it is a common precursor of apoplexy, and frequently averts an attack, and consequently it is not unusual for practitioners when summoned to a case to regard it lightly, and not to employ decided means to arrest the bleeding and prevent a recurrence of it. The following few remarks and cases tend to controvert rather than corroborate these views:—

With regard to its being innocuous to young persons, it is unreasonable to suppose that any hæmorrhage could be otherwise than detrimental to one who is growing; and the following fatal case illustrates the error of the prevalent doctrine, and the practice deduced from it.

Case 1.—A youth aged 13, at a boarding school, was attacked in August with nose-bleeding. Medical advice was sought, but the case was regarded as of trifling importance, and no very decided measures were employed to prevent its recurrence, which happened very frequently during the succeeding six weeks. He was sent home in a very weak state, his nose still bleeding, the blood being very pale and thin; the nostrils were then plugged both anteriorly and posteriorly, and the bleeding arrested, but he sank exhausted on the fourth day after reaching home.

In refutation of epistaxis being salutary in the case of adults, the following case illustrates that it may even be fatal to a man in the prime of life:—

Case 2.—A man aged 37, a butler, in his usual health, having had high words with his wife on the morning of March 25th, was attacked with nose-bleeding. He died in St. Mary's Hospital on the 28th.

But the principal reason urged for not using decided measures for arresting nose-bleeding is that it is likely to avert an attack of apoplexy, and this generally in the entire absence of any other symptom suggestive of such a danger, even if there are other symptoms indicating the necessity or propriety of a loss of blood. Is it not better to arrest the hæmorrhage and employ the remedy of blood-letting *secundem artem*, which is always at command and under control? It seems anomalous that at the present day, when such a revolution has overtaken the medical mind, that an outcry is raised against all forms of blood-letting, arguments should be found in support of not arresting an accidental hæmorrhage.

Six other cases were mentioned, in neither of which were there any symptoms to indicate a threatening of apoplexy. A gentleman aged 56 nearly lost his life by nose-bleeding in consequence of being advised that he ought not to stop it, and consequently no means were used to arrest it. Under these circumstances the bleeding recurred to such an extent that the most severe measures were at length necessary to stop it, and he suffered much in health in consequence. And in another case a man aged 80 was told that the bleeding was an effort of nature, and would be salutary. It was, however, arrested, and the return prevented by keeping the nostrils plugged with cotton wool for three days. He was evidently more benefited by the arrest of the hæmorrhage than he could have been by its continuance.

Blood-letting by means of leeches, had been beneficially employed during the present year in more than twenty cases of head symptoms, and in none was epistaxis present.

In another case, the patient was a child, aged 18 months, in which the nostril was plugged with wool for three days, and there was no return of the hæmorrhage. The affection was therefore peculiar to no period of life, and the indication seemed to be alike in all the cases—viz., to stop the bleeding and prevent its recurrence.

The principal cause of epistaxis seemed to be violent excitement, either mental or bodily, especially during the hot weather, the majority of cases having occurred then.

There was little to be said about internal remedies, as they would be administered according to the views which the practitioner might entertain as to the cause of the attack and the condition of the patient; it was the topical means which were of the greatest importance, and should be employed in all cases, even if the bleeding should have been stayed by any of the popular means which are in vogue. The nostril which has bled, or both, if necessary, should be plugged with cotton wool, which should be retained for three days; but if more decided measures are necessary, the solution of perchloride of iron on wool may be freely used with advantage, and without injury to the pituitary membrane. In cases where the bleeding cannot be arrested by these comparatively simple means, recourse must be had to plugging the posterior nares as well as the anterior.

The mode of doing this is, of course, familiar to all; but a point of detail in connection with the operation was developed in the treatment of one of the cases, which it may be useful to mention:—

The posterior strings attached to the plugs becoming a source of irritation in the mouth of the patient, they were cut away, and in consequence the greatest trouble was experienced in removing the plugs; they could not be reached from behind, and they could not be pushed out from the front. Two hours were occupied in endeavouring to remove one of them. This was at length accomplished, but the removal of the other seemed hopeless, and the patient appeared to be destined to live with a string hanging from his nostril. A simple expedient to relieve him from his dilemma was at length suggested: a string was passed through his nostril with the aid of a piece of catheter as at first, and then the anterior extremity of this was tied to the string hanging from the nostril. It was only necessary then to pull upon the posterior end, and the direction of the original string was reversed and the plug immediately withdrawn. Considering the annoyance which the presence in the mouth of the posterior strings must be to a patient who has to submit to the very unpleasant operation of plugging the posterior nares, if the above device is borne in mind these posterior strings may in all cases be unhesitatingly cut away.

The conclusions arrived at, from the consideration of the above cases, and many others which have been observed, are:—

- 1st. That epistaxis is not an innocent ailment, and should never be so regarded.
- 2nd. That it is not generally, if ever, salutary.
- 3rd. That it does not frequently, if ever, avert an attack of apoplexy.
- 4th. That it is not itself a symptom of cerebral disorder.
- 5th. That it ought always to be arrested as promptly as possible, that being the course most conducive to the health, safety, and satisfaction of the patient, and to the reputation of his medical attendant.

Mr. OWEN thought that in cases of irregular menstruation epistaxis might prove beneficial. Plugging the nostril with perchloride of iron was an admirable remedy in some extreme cases, but syringing with iced water was often quite sufficient. In one case he had found, strange to say, that syringing with hot water had the desired effect, probably by washing away the coagulum.

Mr. BENSON BAKER could not agree with Dr. Ballard as to the danger to be apprehended from epistaxis in most cases. He himself had had frequent attacks of epistaxis, and had done nothing for it. In slight cases he thought no vigorous measures were called for.

Mr. TEEVAN said that, in his opinion, it was much better in most cases of hæmorrhage of a passive kind to leave the clot alone. Iced injections often did more harm than good, because they washed away the clot. The old-fashioned remedy of holding up the patient's arm above his head was often the best means of checking epistaxis. The arms should be held up, however, not by the patient himself, but by some one else, until the patient felt faint. In a case of lithotomy recently performed by him he had checked the bleeding by simply exposing the buttocks of the patient freely to the air. He had often seen bleeding come on in such cases merely because the patient was put into a warm bed and wrapped up in blankets. He thought that the laryngoscope might have proved serviceable in the cases

removed to by Dr. Ballard, when the plugs could not be removed.

Mr. BAKER BROWN, jun., said that epistaxis in females was often a symptom of vicarious menstruation. A fit would almost always be stopped by raising the patient's arm.

Dr. MAUDSLEY observed that he himself was subject to epistaxis, and he would certainly object to having his nostrils plugged for a loss of blood, which seemed often salutary.

Dr. POLLOCK said that congestion of an organ rarely occurred without some constitutional cause for it. Epistaxis would often be best remedied by a purge. One cause of it had escaped mention—viz., the hæmorrhagic diathesis. In some such cases the purely styptic plan proved insufficient, and in such cases the patient should be purged, and the feet of the patient put in hot water. When persons who were subject to epistaxis were red in the face it was probably beneficial. Epistaxis seldom proved fatal in the young, but in the old, and was in such cases probably always a sign of disease of the lungs, heart, or some internal organ. The plan of raising the hand above the head was an excellent one, and he had often employed it with the greatest advantage.

Dr. MUSIET remarked that raising the arm over the head was often useful in other cases of hæmorrhage; such, for example, as hæmoptysis. It was not common to see epistaxis in apoplexy; nor was epistaxis always free from danger. A girl, aged 20, a patient of his, had lost nearly a quart of blood before it could be stopped.

Dr. GREENHOW said that plugging the nostrils was only required, he thought, in some cases of epistaxis, where much blood had been lost. Thus he had seen it save life in the case of an old lady, who suffered from disease of the heart and great vessels. In threatening apoplexy, epistaxis sometimes occurred, and in such cases was beneficial. He thought that in the case mentioned by Dr. Ballard, the using the rhinoscope would have proved of service. It was a pity that the laryngoscope was considered to require special observers, and he thought the instrument should be made use of in general practice.

MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS, IRELAND.

SECOND MEETING, SESSION, 1866-67.

Wednesday, 21st Nov., 1866.

This meeting was largely attended, numerous visitors being present to hear the address of Dr. Stokes, President of the College.

After the chair was taken by the President, the minutes were read by the secretary, Dr. B. G. Guinness.

Among those present we observed:—

Drs. Stokes, Moore, Lyons, Gamie, D.I.G.H.; Fleming, Brady, Fitzpatrick, Benson, De Ricci, McClintock, Johnston, W. D. Moore, Guinness, Belcher, Duncan, Hughes, Hudson, Haughton, F.T.C.; A. Smith, McSwiney, Denham, Cunningham, Sir D. Corrigan, Foot, Dwyer, Churchill, H. Kennedy, Peebles, Gordon, Willis, L'Estrange, Kirkpatrick, Barton, Darbey, Eustace, Croly, Benson, jun.; Little, Sinclair, Atthill, Bennett, Beatty, Adams, Byrne, Head, Law, Kidd, Wharton, O'Rourke, McDonnell, Hardy, Tufnell, Ringland, Geoghegan, Trail, F.T.C.; Wright, W. Smith, Sawyer, &c., &c.

The President then delivered the opening address; of the nature of which we can only say that it was worthy of its distinguished author. As we intend to present our readers with an authentic and accurate report of this address, we need not refer to it further than to say that, in our opinion, it was a model essay of its class; being, in fact, a review of the Society's members and deeds from 1816 to the present time. At its conclusion the Rev. Professor Haughton read one of the most able papers ever written by that distinguished follower of science, entitled "A Scientific Inquiry into some of the Causes that have been alleged to produce Cholera."

The Rev. Professor advocated the contagion theory, and illustrated some of his remarks by reference to Sir D.

Corrigan's Cholera Map of Ireland. He also combated the fog theory of Mr. Glaisher of Greenwich, whose orange and blue mists he dissipated by some strong scientific arguments, Professor Haughton's address, which was characterised throughout by much spirit and genuine humour, was received with attention and applause by the unusually large medical audience which was assembled on this occasion. At the close of Professor Haughton's remarks Sir D. Corrigan responded, and was followed by Dr. Lyons, Dr. Hayden, and others. The meeting concluded at 11 p.m.

ON TRAINING, IN THEORY AND PRACTICE.

In his late work on this subject, Mr. Maclaren makes the following observations:—

The part of the body which receives the smallest share of the exercise in rowing is the chest: it has little or no employment in the muscular effort required for the propulsion of the boat; and this is impressively evident in the results. Not only does it make no advance in development in this exercise, but, if it be exclusively practised, an absolutely depressing effect is experienced. . . . I could at this moment point to men who have had rowing for exclusive exercise since they came to the University, men endowed with an organization capable of the finest development, whose chests have been almost stationary for years, the years during which they should have made the greatest advance, who have now, in fact, the same developments in this region which they brought from school, lingering at 36 or 37 inches, when 40 or 41 were fairly within their reach. The dietetics of athletic trainers are sometimes strangely fanciful, and at other times widely at variance with physiological indications. Whilst pedestrians limit their daily allowance of stimulant to two glasses of sherry, boxers are required to content themselves with the same quantity of port; and rowing men restrain themselves from proper indulgence in fluids, and deny themselves many articles of food that would indubitably contribute to their well-being, under the erroneous impression that asceticism checks the development of internal fat, and endows them with "soundness of wind." In his remarks on diet, Mr. Maclaren observes—"The everlasting beef-steak of former years has now a divided sway with the mutton-chop, and in some colleges it is more varied still. This is a great advantage, and the range may very safely be made wider yet. Eggs, unless poached, are still excluded (why?), and even when eaten the white is rejected. A man in training, with his dread of fat, would be shocked to find that in eating the yolk he has swallowed what is little more than a ball of oil, and in rejecting the white he has rejected an article of almost pure albumen, the special pabulum of the muscular tissues. . . . The importance of an abundant supply of vegetables is often lost sight of. The mere drinking of water or other liquid will not entirely supply the want in the blood for moisture, at times when it is often and largely eliminated from it; it is desirable that a certain amount of fluid, proportionate to the amount and nature of the solids, should be slowly extracted in the ordinary processes of digestion from the solids themselves, and of this vegetables contain a large proportion; moreover, the inorganic substances which they contain, and which we know to be essential to the health of the body, are not attainable in the same form from any other source. A fair proportion of vegetables is therefore absolutely necessary to the healthy condition of the body; not rice and sago, but actual roots and leaves, and green seed-pods; of these let men freely partake, avoiding all fanciful selection." In the appendices to his essay, Mr. Maclaren gives a table showing the digestibility of certain articles of food, but he omits to explain the means by which he has arrived at the conclusions therein recorded.

ARMY MEDICAL SCHOOL.

IN consequence of the grave rumours that have recently appeared in the newspapers, the Professors of Netley have deemed it incumbent upon them to put forth a statement. This they have done in the form of a letter to the Editor of the *Pall-Mall Gazette*, of which the following is a copy:—

"Sir,—We, the undersigned Professors of the Army Medical School, have had our attention called to an article in the *Pall-Mall Gazette*, which was reprinted in *The Times* of the 9th instant, headed 'The Medical Military Service.' As this article contains statements reflecting unjustly on the character and attainments of gentlemen who have passed and of those who are now passing through the course of instruction in the Army Medical School, we feel it to be our duty to request space in your paper for some observations on it. While it is unhappily true that two of the candidates for commissions were a short time ago dismissed for a grave breach of discipline, it is unfair to others, who had nothing whatever to do with the misconduct of the offenders, to assert that 'the present batch of students exhibits this peculiarity of national distribution (i.e., they are mostly Irishmen) in common with others of the last few sessions, but it seems to have a greater variety of *mauvais sujets* than usual.' Now, in reply to this we beg to say that, from the opening of the Army Medical School until now, the strictest discipline has been maintained. When the Army Medical School had its home in Chatham the general officer commanding the garrison declared that no class of officers under his orders had given him so little trouble as the young men going through the probationary course in the Army Medical School at Fort Pitt. This is the thirteenth session of the school, and we declare that, from first to last, only two examples of serious misconduct have taken place, including the late occurrence, both of which were punished by immediate dismissal. We submit, therefore, that the Army Medical School, in the conduct of the gentlemen under instruction, will bear a favourable comparison with any of the Universities or other places of public instruction, military or civil, in the three kingdoms. With regard to the gentlemen candidates now in the school, we assert that, so far from being a set of men with a 'large proportion of *mauvais sujets*' among them, they, as a body, are men of sound education, correct and gentlemanlike in their conduct, attentive to their duties, and in a high degree submissive to the requirements of military and academic discipline. We have the honour to be, sir, your most obedient servants,

"W. C. MACLEAN, Deputy-Inspector-General,
Professor of Military Medicine.

"E. A. PARKES, M.D., F.R.S., Professor of Military Hygiene.

"THOMAS LONGMORE, Deputy-Inspector-General,
Professor of Military Surgery.

"W. AITKIN, M.D., Professor of Pathology.

"Army Medical School, Royal Victoria Hospital, Netley,
Nov. 13, 1866."

Reviews.

ON THE NATURE OF CHOLERA, AS A GUIDE TO TREATMENT. By WM. SEDGWICK, Esq., M.R.C.S., Surgeon to the Marylebone Dispensary. Walton and Maberly. 1866. London.

MR. WM. SEDGWICK is an author well known to the medical public for the accuracy of his observations and the soundness of his reasonings. His researches into the laws of hereditary transmission of diseases have done much to throw light upon a very difficult subject. The object of the work on cholera, before us, is to illustrate the theory which refers that disease to functional derangement of the

central parts of the sympathetic system of nerves, excited through the medium of the stomach. This theory the author considers to be the only one which satisfactorily explains the nature of cholera. He shows, firstly, that a congested state of the lungs is not found after death from collapse, and that the lungs are contracted and empty, and, on an average, have together lost twenty ounces of their weight. This condition of the lungs is fully accounted for, as the author observes, by the diminished quantity of air inspired. Mr. Sedgwick is disposed to consider the stomach to be the centre of the affection in cholera, and in illustration of his meaning he adduces the example of the effects of a severe blow upon the epigastrium, or the symptoms which so suddenly arise in some cases upon the injection of cold water, while the body is perspiring. He also draws an interesting parallel between the symptoms observed in cholera and those seen in perforating ulcer of the stomach. In both of these cases there is usually rapid death, whilst the mental faculties remain intact, the skin is cold, the face sunken, there is precordial oppression, urgent thirst, the pulse is imperceptible at the wrist, there is diminished respiration, and suppression of urine. These facts all point towards a sudden functional derangement of the centre of the sympathetic nervous system, the solar plexus. After remarking on the singular fact that in cholera prolonged suppression of urine does not lead to coma, he observes that there is no evidence to show that any of the effete matters ordinarily present in the blood, as carbonic acid and urea, are accumulated in it previous to or during the collapse; and with regard to the theory of a specific poison existing in the blood in cholera, he considers the argument for this to be quite inconclusive. In this we do not quite agree with Mr. Sedgwick, since he will find it no easy matter to account for the spread of cholera over the earth, except by supposing it to be infectious to a certain extent, although not so much so as typhus fever, &c. Mr. Sedgwick, however, makes out an admirable case for the non-contagious view. He observes, firstly, that cholera discharges have been often swallowed without causing the disease, and that neither the blood nor the discharges seem capable of infecting others. The author with justice objects to the assumption that cholera is always preceded by diarrhœa; and this point now seems fully to have been set at rest by recent experiences in Paris, London, and Malta. He considers the fact of cholera evacuations being alkaline as an important matter in the inquiry into the nature of the disease, and observes how frequently there has been complete absence of any peculiar lesions of the intestines after death from cholera. He considers that the diarrhœa is due to the fact that the gastrointestinal mucous membranes are no longer under the influence of the nervous system and ganglia.

On the head of treatment the author is very explicit. He first draws a parallel between the statistics of various methods of treatment, from which it would seem to result that the most unfavourable results have been obtained by the two opposite plans of treatment by castor-oil and by dilute sulphuric acid. The treatment by calomel and opium seems to have yielded better results. He appears then to abandon all hopes of obtaining success either by the astringent or eliminate plan of treatment. Three other methods of treatment remain after these have been exhausted—viz., bleeding, saline injections, and galvanism. Of these our author recommends the first alone, as being the only one which has been proved to be beneficial, remarking that the conditions of the blood in cholera is relatively that of hyperæmia; since there is an excess of blood-disks in it. He adduces several cases, which tend to show the value of that now almost forgotten practice of venesection, and mentions that it was reported that, when bleeding was employed in the Bengal Presidency, it was found to be much more successful than any other remedy; "a lieutenant-colonel of

artillery in Egypt, in 1832, bled with his own hand more than one hundred soldiers at the beginning of the disease, and saved nearly all." The author asserts that in no case is bleeding likely to prove so serviceable as when it is performed at an early epoch, before collapse has set in. He is in favour of venesection to the extent of fourteen ounces. In conclusion, Mr. Sedgwick earnestly advocates attention to hygiene, and strenuous attempts being made towards rendering our towns less dangerously overcrowded by their poorer inhabitants. The work is a most valuable one, the principles it contains are clearly stated, and we have the utmost confidence in recommending its perusal to all who desire to come to a rational conclusion as to the nature and treatment of cholera.

THE HARVEIAN ORATION, 1866. Delivered June 26.

By GEORGE E. PAGET, M.D. Cantab. Pp. 49. Cambridge and London. 1866.

The Harveian Oration, being now delivered in English, becomes available for the perusal of a much wider circle of readers than that which formerly perused the Latin compositions, and, like the Hunterian Oration at the College of Surgeons, the annual discourse at Pall-Mall has assumed the form of a graceful tribute, in the vernacular tongue, to the memory of those Fellows of the College who have made themselves conspicuous by their labours or their discoveries. There are perhaps some *laudatores temporis acti*, and we ourselves are among the number, who would have preferred that the London College of Physicians had preserved their prestige for the purity of their Latin; but, be this as it may, there is no doubt that Dr. Paget would have been equally at home whether his discourse had been in the ancient Roman or the modern English language. This Harveian Oration is in every way creditable to his good taste, and is quite worthy of the College.

OSTEOLOGY: A Concise Description of the Human Skeleton, adapted for the Use of Students in Medicine, accompanied by an Explanatory Atlas of Plates. By ARTHUR TREHERN NORTON, Assistant Lecturer in and Demonstrator of Anatomy at St. Mary's Hospital School. London: Hardwicke. 1866.

"OSTEOLOGY," as Mr. Norton remarks in his preface, "is the basis of anatomy," and this assertion cannot be too often repeated for the warning and the edification of the medical student. For this reason alone we should welcome any book having for its object the inculcation of a correct knowledge of the bones, but more especially when it comes in so cheap and elegant a form as it does in the two little volumes before us. The one contains the letterpress, and the other the plates, which are twenty in number, each in most cases containing several illustrations, so that the student can have both open before him, and can see the object described while he is reading the description; and he will do still better if he has also at the same time before him the actual bones, so that he can compare the actual structures with their artistic delineation. In order still further to facilitate the acquisition of osteological knowledge for the student, each plate is accompanied by a side description, not only including the processes, grooves, foramina of the bones, but also the attachments of the muscles and the ligaments, and any other particulars suggested by the object represented. Thus the Atlas in itself becomes a complete compendium of anatomical knowledge; and although it will not, of course, supply the want of the bones themselves, it will serve admirably to refresh the memory, the more especially as its size and portability suits it very well for a pocket companion. The pages are tinted, the explanations are clear and concise, and the engravings are in the highest style of art, and it is

evident that no expense has been spared to render the book in every way adapted to the very useful end for which it is designed.

TRANSACTIONS OF THE PATHOLOGICAL SOCIETY OF LONDON. Volume Seventeenth: Comprising the Report of the Proceedings for the Session 1865-66. London. Printed for the Society. 1866.

THE present volume of these "Transactions" is by far the most valuable, both in the abundance and variety of the information it contains, and in the beauty and perfection of the plates and woodcuts by which it is illustrated, of any of the annual publications hitherto issued by the Pathological Society. All its predecessors have progressively exhibited the growing importance of the practical study of pathology, and have been got up in a manner highly creditable to the industry and zeal of their respective editors, but this surpasses them all. The nature of the objects exhibited at the periodical meetings of the Society, and the discussions attending their presentation have been detailed in our own pages in regular order, but the "Transactions" display the same particulars carefully arranged under their respective heads, and illustrated, where circumstances permit, with copious plates and drawings. The engravings are all in the highest style of art, but we may especially notice the representation of Dr. Morell Mackenzie's case of Cancer of the Thyroid Gland, that of Mr. W. Adam's case of Tumour of the Right Humerus, and those of Mr. Jonathan Hutchinson's case of Circular Fracture of the Base of the Skull; but perhaps the most extraordinary, both in the skill with which they are designed and executed, and in the strange and rare monstrosity which they illustrate, are two engravings showing Mr. E. Bickersteth's case of Disease of the Bones of the Cranium, in which the whole of the skull, the lower jaw, the hyoid bone, and the febula, were overgrown with an immense mass of osseous matter, constituting one of the most hideous, but, at the same time, interesting cases of deformity which perhaps was ever seen.

We merely conclude by repeating our opinion that this volume of "Transactions" is the most valuable ever issued by the Pathological Society.

THE GLASGOW MEDICAL JOURNAL. November, 1866.

THERE are here three original papers, entitled respectively, "Suggestions for the Logical Use of Hospital Statistics," by James B. Russell, B.A., M.D.; William Leishman, M.D., "On the Treatment of Acute Rheumatism by Blistering;" and J. G. Wilson, M.D., "On Prolapse of the Umbilical Cord." There is one review—viz., on Dr. Scoresby-Jackson's "Note-Book of Materia Medica;" and there is also a "Clinical Record" [concerning Cases of Obstruction of the Bowels; and a Case of Poisoning] by External Use of Belladonna. Dr. Scoresby-Jackson's book here, as everywhere else, comes in for praise and recommendation.

THE MEDICAL MIRROR. November, 1866.

DR. INMAN begins this number with his Third Chapter "On the Preservation of Health," and is followed by "A Quondam Doctor" on "Workhouse Revelations." Dr. Purdon furnishes a paper "On Pemphigus," being the first of his "Contributions to Dermatology," and Dr. Terry of New York, winds up the originals with the conclusion of his account of "The History, Etiology, Pathology, Prophylaxis, and Treatment of Cholera." The "Editor's Letter-box" is a peculiar feature in this journal.

ON HÆMODROMOMETERS. By W. HANDSEL GRIFFITHS. Pp. 8. Read before the Royal Irish Academy, December 11th, 1865.

IN this paper Mr. Griffiths discusses the comparative merits of the hæmodromometer, or instrument for measuring the velocity of the movement of the blood in the arteries, invented by Volkman, and of the modified form of hæmodromometer recently invented by himself. Mr. Griffiths points out four objections to the employment of Volkman's hæmodromometer in physiological experiments. These objections may be summed up as arising from certain defects which, Mr. Griffiths considers, may lead to erroneous observations, by decreasing the velocity of the blood's movement in the hæmodromometer. The chief improvement in the instrument suggested by Mr. Griffiths appears to consist in a contrivance for raising the temperature of the hæmodromometer to that of the blood circulation in the arteries, and in substituting a vacuum for the water employed in Volkman's apparatus. We know not whether Mr. Griffiths' hæmodromometer has been as yet tried, or indeed even constructed or not, but we fear that the great complicity of its parts, and the extraordinary delicacy of manipulation its use would require, will prevent its replacing the more easily employed hæmodromometer of Volkman. Mr. Griffiths, however, deserves much credit for the ingenuity displayed in the invention he describes in the paper now before us, and we trust he will soon afford us another opportunity of bestowing more unqualified approbation on some simpler form of hæmodromometer.

London Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 28, 1866.

THE TESTIMONIAL TO DR. RICHARDSON.

It is unfortunate that there exists no public or recognized method of rewarding the men who labour in the field of what may be called abstract science; and although the researches of those who thus exercise their intellectual powers are often productive of the most important and useful practical results to the community, it too often happens that the harvest of material success is reaped by others who have had nothing to do with sowing the seed. In an active country like our own, where men are constantly engaged in the pursuit of daily gain, or in the acquisition of competence, it is perhaps natural enough that most persons should prefer to travel along the roads which lead most rapidly to the desired goal, and should neglect those comparatively unfrequented paths where a few wayfarers are struggling on, almost in solitude, towards the development of some great idea which may be pregnant with the most beneficial consequences to mankind; but it is, nevertheless, essential that in a civilized state of society the value of such labours should be recognized, and that such substantial encouragement should be offered to their originators as may enable them to pursue with increased zeal their silent and unostentatious, but meritorious career.

In some respects our country is quite rich enough to remunerate those who devote themselves to intel-

lectual labour, and the munificence of many of our ancestors has amply endowed several institutions having for their object the promotion of learning; and the enormous revenues accumulated by the Church in former times, and, to a great extent, still enjoyed in the present day, were originally designed almost as much for the encouragement of letters as for the advancement of religion. But it is too well known that many of these endowments have lapsed into mere sinecures, conferred as favours on political adherents or personal friends, and that the objects originally contemplated have been in most cases altogether overlooked. If such be the case with the pursuits of literature and theology, the anomaly is still greater with those modern branches of knowledge for the encouragement of which there are no endowments at all, and the cultivation of which is consequently left to those who are bold enough to undertake the task.

In the pursuits immediately connected with our own profession, it has been found by sad experience that many of those who have laboured most earnestly in establishing the bases of scientific medicine, have obtained a far less substantial recompense than those who have only followed the beaten track; and the consequence has been, that although many active workers in the domain of physiology may be counted in our ranks, their numbers are gradually thinned by the secession of even the most distinguished into the more lucrative sphere of practice. These persons are wise in their generation, for it is a matter not only of difficulty but of impossibility to combine the close study of experimental philosophy in any department with the daily demands of a medical life, and as the one course leads only to fame and the other to pecuniary emolument, the choice of the alternative is easily explained.

The remarks we have made apply with particular force to the claims of Dr. RICHARDSON, in whose behalf a Testimonial is now being raised among the Profession and the public at large. Although still comparatively a young man, Dr. RICHARDSON has already made himself most honourably conspicuous as an energetic devotee to Physiological Science, and by the number and variety of his experiments and his deductions he has increased to a very wide extent our knowledge of the operations of life. His researches on the circulation of the blood, and on the cause of the coagulation of that fluid, on the formation of fibrinous clots in the heart and great vessels, and on the effects of anæsthetic vapours on the living body, and his latest discovery of an efficient method of applying local anæsthesia, have all challenged admiration, not only for the boldness and originality with which the researches were designed, but for the patience, perseverance, zeal, and talent, with which they have been carried out. In the instance of the application of local anæsthesia, by which the benefits of anæsthetic vapours are secured, while their dangers are avoided, he has obtained for his discovery the merit of practical

utility as well as ingenuity of contrivance; and a country like our own, which, however much it may have neglected the claims of mere abstract philosophy, has shown itself fully appreciative of tangible benefits, ought to estimate this last boon as it deserves.

From the advertisement which appears in our pages this week, it will be seen that a large and influential portion of the Medical Profession, and many of the general public, have already contributed to the Testimonial, which it is proposed should be presented to Dr. RICHARDSON, in recognition of his many scientific labours, but chiefly for his successful invention of the method for producing, without danger, local insensibility to pain in surgical operations.

The Committee which has been formed for carrying out this object is exceedingly numerous, comprising the names of medical practitioners and other persons of influence in all parts of the Kingdom, and it is hoped and believed that subscriptions will be received from the members of the profession and the community in all parts of the world, so that the Testimonial shall take such a form as to be not only a recognition of what Dr. RICHARDSON has already done, but a substantial means of encouraging him to pursue his scientific researches.

The Chairman of the Committee is Mr. JAMES PAGET, F.R.S. of London, and the Honorary Secretaries are Mr. DUNN, of Norfolk-street, London, and Mr. R. W. DUNN, of Surrey-street, London.

HOSPITAL REPORTS.

IN reply to numerous queries, we have much pleasure in stating that the Clinical Reports, or "Clinique" of the Richmond, Whitworth, and Hardwicke Hospitals, which we furnished our readers for several months together during the greater portion of this year, will be resumed almost immediately, and will, we hope, be continued weekly for some time to come. Hospital reports and other Clinical matters should be printed on Thursday at the latest, so as to allow time for revision previous to their insertion on the Wednesday following. Hence we need scarcely urge the importance of having the manuscripts in our hands as early as possible.

Notes on Current Topics.

YELLOW FEVER AT SOUTHAMPTON.

It was impossible to confine the passengers on board the *Atrato*, in which quarantine was ordered, without giving rise to much complaint. We regret that, on the Privy Council determining to adopt the strictest measures, no steps should have been taken to make the burden fall as lightly as possible on the unhappy voyagers, whose delight at reaching home would thus have been destroyed by the order forbidding them to land. We publish in our correspondence page a letter on this subject from Dr. E. Hearne of Southampton, to which we would draw especial attention. Dr. Hearne is well

known to have bestowed great attention on this subject, and as a strong non-contagionist his arguments are worth consideration.

We should have been glad, indeed, had the writings of some of our contemporaries exhibited an equal familiarity with the subject. It is easy to understand how occasionally political journals may admit alarming statements into their columns, but it is altogether inexcusable for a professedly medical organ to play fast and loose with such a subject.

Mr. Simon, upon whose advice the Privy Council is supposed to act, has reported that "yellow fever is a malarious rather than a truly zymotic disease;" that it is "of the nature of ague rather than of typhus;" that the "ship which spreads infection does so irrespectively of the persons who are in it;" and that a proper disinfection of the ship "would probably suffice to prevent" an outbreak. Now, we must say, that with this report before them, it is passing strange that the Lords of the Privy Council should have deliberately confined, for several days, on the ship they supposed to be infected, a number of persons, who, according to their own adviser, could only possibly possess "a very scanty and transient power" to spread the disease. At the least the unhappy persons should have been provided with suitable accommodation during the period of detention, and they should all have been at once removed from the "infected" ship.

Since the above was written we learn from Southampton, under date of Friday last, that the vessel was released from quarantine that morning. The *Atrato* arrived in dock at one P.M. on that day, to the great delight of both crew and passengers.

ST. MARY'S HOSPITAL STUDENTS.

A PARAGRAPH, for which there was scarcely any foundation, has been going the round of the papers, in reference to the conduct of some students of St. Mary's Hospital at the visit of a coroner's jury to the dead-house. One of our contemporaries, the *Pall-Mall Gazette*, has stigmatised these gentlemen in terms which could only have been appropriate had the representations of the facts been strictly correct. This is not the first time the *Pall-Mall*, affecting intimate knowledge of medical matters, has discovered a mare's nest. We recommend our contemporary, before again taking up abusive language, to make sure that the supposed facts are not mis-stated.

THE QUEEN V. ST. BARTHOLOMEW'S HOSPITAL.

THIS trial, which has been determined during the week, is not of any great importance to the profession. Its object was, in fact, merely to determine with whom rested the appointment of President. The Corporation of the city of London claimed the privilege of nominating him, as a municipal right, while this claim was resisted by the donation governors. A vast amount of learning and interesting customs were brought to light during the trial, and we presume the expense was not inconsiderable. The civic authorities have lost the cause, which was decided in favour of the governors, who have thus established their right to elect a President. It may be added that this decision will govern the future elections in all the large city hospitals.

NURSING SISTERHOODS AND KING'S COLLEGE HOSPITAL.

A DIFFICULTY has occurred at this institution, which has been anticipated by not a few interested in the question of sisterhood nursing. It would appear that the chaplain has failed to give complete satisfaction to the sisterhood, and that he is not sufficiently ritualistic in his practice. Nothing could be more improper than a theological controversy conducted in this manner, and however ably sisterhoods may perform nursing duties, we hold that they ought to be imperatively excluded from interference in other departments. If suffered to call the chaplain to account they will, perhaps, soon have the impertinence to interfere with the physicians and surgeons. It is not unlikely the hospital may sustain considerable pecuniary loss by the officious attempts of the sisterhood to control the action of the chaplain. We know nothing for or against this clergyman, but we certainly do protest against his being held responsible for the mode in which he performs his duty to any one else employed in the hospital. There are whispers that the "craven charity," which has been recently given to King's as a representative of the "pest house," is likely to be withdrawn should the quarrel be taken up by the lay governors. Let the authorities take warning in time, and stringently confine the sisterhood to their own duties. We protest against our noble hospitals being made an arena for theological disputes, and if this should be the usual result of placing the nursing in the hands of sisterhoods, the experiment must be given up, and all such bodies systematically excluded from lending their aid to these charities.

UNIVERSITY COLLEGE.

THIS institution was founded, as is well known, expressly to furnish secular education only. Great surprise is therefore expressed at the announcement that Mr. Martineau, whose claims are well known, should have been held ineligible for the chair lately resigned by Dr. Hoppus.

It is said that Mr. Martineau's Unitarianism has led to his exclusion. Unless the Council are prepared to prove that this is not true they have inflicted a blow on the College's reputation, from which it will not readily recover. That a Unitarian should be ineligible for a Professorship in a professedly unsectarian college is a simple absurdity. Will the Council give an explanation of the conduct which causes so much scandal?

DR. MARY E. WALKER AND THE MEDICAL STUDENTS.

A NUMBER of our contemporaries, condemning the disturbances at Miss Walker's lecture, imputes the whole blame to medical students. They seem utterly to ignore the fact that if a rowdy chooses to dub himself medical student there is no law to prevent his doing so. For our part we trust that the students of the London Hospital were generally much better employed than they could have been at St. James' Hall on the evening in question. We beg to ask our contemporaries whether, if some lecturer on the freedom of the Press should uphold a rigorous censorship, and thereupon get hissed, ought it to be at once concluded that the signs of disapproval necessarily came from a compact body of editors, sub-editors, and penny-aligners?

Correspondence.

THE MEDICAL CLUB.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your correspondent, "An Intending Member," in THE MEDICAL PRESS AND CIRCULAR of October 31st, alludes, very properly, to the necessity for confidence, on the part of members about to join the Club, towards those entrusted with the management of its affairs; and it is a matter of extreme congratulation that the gentlemen constituting the Committee will form a sufficient guarantee on this head.

Your correspondent next alludes to the necessity of the election on the Committee "of gentlemen who would really take an active part in the management, as well as some whose professional renown will shed a lustre over the whole body." Here, again, we are singularly fortunate, for out of the Committee of six chosen to represent the various sections of the profession and laity, four are already members of other clubs, and therefore well versed in the management of similar institutions, whilst some have time and large practical experience to bring to bear upon the concerns of the Club.

It was decided, at the meeting on the 8th instant, that the Club should be called "The Medical Club;" and for many reasons this is the best name that could have been chosen, for it will always preserve its distinctive character, and as, by its constitution, it will admit of the election of "labourers in other branches of science," it will, in time, come to be regarded as the representative, in the metropolis, of scientific men generally.

"The procuring a house and making a start" will form, as your correspondent justly remarks, "the first practical step" in the progress of the institution. Your correspondent says that, "as soon as 200 members are enrolled, we might start in a small way." In proof of the determination on the part of the Committee to start, in a safe way, it is worthy of remark that we have already enrolled upwards of 400 members, and have no intention of commencing until that number is considerably increased.

We have, moreover, anticipated the advice of your correspondent, as illustrated by "the young man going into lodgings;" for, by the kindness of Sir Charles McGrigor, we have already gone into lodgings at 17, Charles-street, St. James', where the business of the Club will, in future, be conducted; but we have this great advantage over the young man in question, that our worthy landlord demands neither rent nor taxes, and seeks no other reward than the love he bears towards the profession, and the desire to see a Club established for the comfort and convenience of its members.—I am, sir, your obedient servant,

LOBY MARSH, Hon. Sec.

November 16, 1866.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As you state in your leading article on this subject that your columns are open for discussion, I beg first of all to thank you for your very judicious observations, and then to ask leave to protest against the proposal of starting near Cavendish-square. It is true that locality would be central for a good many eminent practitioners, but do not forget how inconvenient it would be for the country members. The Club ought to be near a railway station. For this purpose Charing-Cross is the most central. We should then be near the palatial homes of the other clubs in Pall-Mall—an advantage not to be gainsayed. Moreover, was it not advertised at first that we were to be near the College of Physicians? I hope an attempt will be made to secure accommodation amongst the other clubs.—I am, sir, J.K.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your reporter has done full justice to the speech of Sir Wm. Fergusson, on which you commented last week. It is but fair to add that other very eminent and influential men warmly supported the proposal, amongst whom may be named Dr. Richardson, Mr. Propert, Sir C. McGrigor, and others. Perhaps you did well to select the speech of the President. At any rate it was not invidious. Only let it be known that the movement commands the very highest support. I am desirous of directing the attention of the Managers to the very practical and prudent sugges-

tions of "An Intending Member," which appeared in your number of the 7th inst. Nothing can be more business-like than the proposals he brought forward. Avoid a flash in the pan; begin quietly; take "An Intending Member's" advice; "first creep, then run." We must then succeed.

ALIIQUIS.

OXALATE OF IRON A NEW TONIC.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Allow me to draw your attention to a preparation of iron, which has been much neglected, if not altogether overlooked. I refer to the oxalate of the protoxide of iron. Having lately used it in cases requiring the exhibition of a compound of the metal, I observed that it was borne with remarkable ease by the stomach, possessed little if any astringency, and produced the usual constitutional effect with sufficient rapidity.

The salt is easily prepared by adding a solution of protosulphate of iron to an excess of oxalate of ammonia solution containing a little free oxalic acid, a yellow precipitate is thrown down, which is the compound in question; this should be well washed and then dried. By having an excess of oxalic acid present any per-salt formed is held in solution. The precipitate yielded on analysis results agreeing with the formula $\text{Fe O, C}_2 \text{O}_3 + 4 \text{HO}$, and therefore contains one-third of its weight of oxide of iron, one-third of oxalic anhydride, and the rest of water. The salt when prepared as above directed, is a fine powder of a straw-yellow colour, almost devoid of taste and singularly slow to oxidise in contact with the air. It is slightly soluble in water but more easily acted upon by a dilute acid, and is decomposed by the alkalies or their carbonates. When burned in the open air it leaves a residue of pure peroxide of iron in a condition particularly favourable for the production of *fer redit*. In conclusion, I may remark that the oxalate of iron requires but three atoms of oxygen for its complete oxidation in the system, whereas for a given weight of iron the tartrate of the peroxide needs ten equivalents and the citrate eighteen of oxygen to effect the same end.—I am, sir, yours, &c.,

J. EMERSON REYNOLDS.

Boosterstown, November 15th, 1866.

THE SYMPTOMS AND TREATMENT OF CHOLERA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—In my next paper I propose to lay down the symptoms of epidemic cholera, as it appeared in this country on former occasions, and then contrast them with those of the present outbreak, in which there is a marked difference.

Your obedient servant, JOHN LENEX.

The public have been informed, through the medium of newspapers and printed placards, and the profession by the productions of medical men, that the first symptom is painless diarrhœa. It certainly is not always so. I have met with many cases in which diarrhœa did not show itself, but violent and profuse vomiting persisted to the last, and in the most hopeless forms, commonly, neither vomiting or purging take place. The origin of the disease consists in a morbid poison (whether animal or vegetable, doubtful), which, being inhaled, is succeeded by symptoms varying in degree from those barely perceptible to the person, to those incompatible with the persistence of life, and over which medicine has no control.

When the pestilence lights as a cloud on a locality, almost all feel its poisonous influence, some in a mild, others in a severe form. Its first impression is on the pneumogastric nerves through the medium of the lungs. The symptoms are the following, proportionate to the amount or concentration of the poison inhaled, and the predisposition of the individual at the time of seizure:—

First grade.—Nervous thrill or shudder; constriction of the chest, with oppressed breathing; sense of nausea; nervous fright. The person feels a sensation of chill over the surface of the body, then succeed flatulent rumblings of the bowels, loss of appetite, and sleep. The patient is agitated and restless, looks pale, possibly may have a faint blue circle around the eyes, pulse quick and weak, and slight frontal headache. On the irruption of hæmorrhœa, most medical men experience the disease in this grade, from the poisonous efflu-

vium arising from the sick. These symptoms may proceed no further, yet may continue for days, or during the stay of the epidemic in the neighbourhood, if medical treatment be not had recourse to.

Treatment.—Let the patient inhale diluted oxygen gas or nitrous oxide gas for a short time. This alone has removed the symptoms. The feet and legs should be bathed in water as hot as bearable for five minutes, then rubbed diligently with a coarse rubber, take to bed and give a mustard emetic. The probability is, these means will be succeeded by increased vascular action on the surface of the body and full perspiration. Should not sleep set in, give from half a grain to three-quarters of a grain of acetate of morphia, with thirty drops of chloric ether in an ounce of camphor julep. This will procure tranquil sleep for some hours, and the patient awakens in his usual good health; but some, not considering themselves so ill, will not submit to this treatment, and others, whose avocations will not admit of it. Then let the patient occasionally smell ammonia or aromatic vinegar, live well, take for breakfast meat and a glass of ale, in lieu of tea or coffee; fresh meat, roast or boiled, and a glass of good brandy or whisky punch at dinner; avoid unripe fruit and stale vegetables, and the less supper the better; keep warmly clad, eschew all depressing agents, smoking to excess, and intemperance of all kinds; if possible, move to a distance from the infected district, and enjoy agreeable society, &c. Give the following:—

R Pulv. capsici.

Camphoræ, aa. gr. vj.

Assafœtidæ,

Extr. hyoscyami, aa. gr. xvij.

M. Ft. pil. xij., capiat i., 3tiis. horis.

PROPHYLACTICS.

Observe strict cleanliness, keep much in the open air, warm clothing, generous living, avoid excesses of every kind, fatigue, &c., depression of spirits; be not out over-early or late, avoid damp and wet, do not leave the house in the morning with an empty stomach; for breakfast a chop, with a portion of onion and a glass of ale; take each morning some aromatic bitter tincture—viz., a teaspoonful or two of tincture of gentian in camphor julep, or a grain or two of sulphate of quinine in cinnamon water; let a weak solution of chlorine be diffused through the house during the prevalence of the epidemic. The labouring poor should eat an onion and bread on leaving their houses in the morning, and also at breakfast hour. Whilst the epidemic lasts, purgative medicine should be scrupulously avoided, especially the salines, or such as produce watery evacuations; a dose of medicine, which at another time would act gently but once or twice, probably under this condition of atmosphere would produce colliquative hypercatharsis. If constipation exist, an enema of hot water, or soap-and-water, or a mild form of pill or draught—viz.:—

R Camphoræ,

Pulv. capsici, aa. gr. iij.

Pil. rhei comp. ʒj.

M. Ft. pil. vj., capt. i., 3tiis. horis. ud effect.

R Æther. chlorici, gtt. xx.

Ol. ricini.

Tinct. rhei comp. aa. ʒiij.

Aquæ cinnamon. ʒi.

M. Ft. haustus.

Second Grade.—The second grade is in many cases the primary, owing to the greater paralyzing influence of the poison on the lungs and nerves of organic life from predisposition—viz., advanced age and debility, infancy, persons living on scanty and unwholesome food, want of sufficient clothing, and inmates of too crowded and badly ventilated dwellings, exhaustion arising from any cause, especially intemperance. Symptoms are those already enumerated, but much severer, superadd collapse and terrified countenance, frequent sighing, greater sickness of stomach, noise in the ears, vertigo, loss of muscular power, heat and pain at pit of stomach, flatulent colic (cramp of stomach commonly precedes vomiting, cramps of the extremities rarely precede, but are usually consequent on, one or more evacuations from the bowels), slight cramps of the fingers, legs, and toes, pulse weak and small, sometimes intermitting, damp and clammy condensation of the surface of the body, soon the symptom painless diarrhœa succeeds, but not yet, for the first and second evacuations are the ordinary frequent discharges accompanied

with griping, quickly followed by the characteristic painless hæmorrhœa or passive discharge of white blood, the patient may have but one or two copious serous evacuations, by which the congestion of the internal organs become relieved, equilibrium is re-established, and normal circulation renewed; the disease may stop here, or from increased sickness the stomach distended by serous hæmorrhage from its own mucous surface and that of the œsophagus, abundant serous vomiting takes place, and thus the internal congestion is removed, and more calculated is vomiting to restore reaction, take off congestion, and re-establish heat and equalisation of circulation from the convulsive efforts used in it; the disease may also stop here, thus in either way effecting its own cure. But this favourable termination may be said alone to occur in the robust, previously healthy, and persons of temperate habits.

Treatment.—If called to see a patient, circumstanced as now described, our object should be to aid in keeping up a steady reaction; this must be done by the warmth and quiet of bed. Let him have some brandy and water, and give the following:—

- Creasotonis, gr̄. xij.
Tinct. capsici, ʒi.
Æther chlorici, ʒij.
Tinct. cardam. comp. ʒi.
Mist. camphoræ ad ʒviiij.
M. Capt. ʒi., 2dn. hora.
℞ Pulv. alumenis ʒij.
Tinct. opii. gr̄. xxx.
Aquæ frigidæ, ʒviiij.
M. Pro enema.

Use a gutta-percha enema bag, with a tube from twelve to eighteen inches long.

From the nature of the attack, so severe, the derangement of the digestive mucous surface and accompanying disturbance of all the vital organs, leaves them for a time incapable of discharging their functions effectively, so that our attention must be directed to the restoration of healthy secretions. For this purpose

- ℞ Pulv. opii gr. i.
Capsici, gr. vj.
Aloes hepatici.
Pil. hydrargy, aa. gr. xij.

MEDICAL TRIALS.

BAIL COURT, LONDON.

(Sittings at Nisi Prius, before Mr. JUSTICE BLACKBURN and a Common Jury.)

ABSOLON v. STATHAM.

THE declaration stated that the defendant was charged with assaulting the plaintiff, and administering to her chloroform and extracting six of her teeth. The defendant pleaded "Not Guilty," and leave and license.

Mr. Chambers, in opening the case, said it was one of the greatest importance, with reference not only to the demand made by the plaintiff, but to the general duties of surgeons and medical men in the treatment of those who resorted to them for advice and assistance when any kind of operation was required. More than two years since the plaintiff, who was in an humble position in life, gained her livelihood by attending different ladies and making up their dresses at their own houses. She had suffered from pain in her teeth, and in 1864 she was recommended to apply at the Great Northern Hospital, where there were persons who extracted teeth without pain. She accordingly went there, and saw Mr. Byers, one of the surgeons, who recommended her to go to Mr. Statham, who practised at 60, Wimpole-street. She accordingly went to the defendant, who looked in her mouth, and said he should like to take out her teeth. She,

however, objected. He then intimated that he should like to administer chloroform, but this she decidedly objected to, stating that she had taken it some years since, and had suffered so much that she would never take it again. She afterwards saw him again, but on the 17th August she met the defendant at the Great Northern Hospital. He desired her to open her mouth, and while she was doing that Mr. Byers came in, and without any intimation or caution he placed a handkerchief over her mouth, and then administered chloroform to her. The result was that she became insensible for a time. When she recovered consciousness she found the defendant tugging at her fifth tooth. She began to scream, but the defendant persisted in proceeding, and extracted six teeth, and seized her by the throat in such a manner as to cause her great pain, which continued for a great length of time. She went to the Royal Free Hospital, to other hospitals, and eventually to Margate. She was now in quite a shattered condition, and unable to continue her occupation. She was permanently incapacitated, and, as he submitted, through the violent and improper conduct of the defendant. For this she now appealed to a jury for damages.

Mrs. Absolon—In August, 1864, I went to the Great Northern Hospital for advice. I was suffering from nervous debility and the toothache. I had seen Mr. Gant, of the Royal Free Hospital, who gave me advice. I saw Mr. Byers at the Great Northern Hospital, and, at his recommendation, I went to the defendant in Wimpole-street; and the next morning he examined my mouth and my condition generally. He gave me something to apply to my teeth. Upon a subsequent occasion he proposed that my teeth should be extracted. He said he would not give me much pain if he extracted one. I said I could not bear it, as I had suffered already. He then proposed chloroform. I said I could not take it. He said he thought I could. I said I had taken it many years before, and had nearly lost my life. He said he thought I could take it. He said I should go to the Great Northern Hospital and see the surgeon there. I went there soon afterwards to see Mr. Byers for nervous pains in my head. He told me that he had seen Mr. Statham. On the 17th August I saw Mr. Byers, who took me to Dr. Cruicknell, who examined me, and spoke of chloroform. I told him I could not take it, as I had taken it before, and it nearly killed me. Dr. Cruicknell asked how I knew, and if the doctors told me so. I said they had told my father. He said: "I would let them take out a tooth without taking it." Then he said the mouth was in a very inflamed state, and he thought I could take a little. I was frightened, and Mr. Byers ordered me out of the room, and to wait in the waiting-room; and then Mr. Byers told the porter to send me to him. I then said to Mr. Byers: "If they give me chloroform they will kill me; do not let them kill me." He left me, and the nurse came to me. I was requested to go to bed, which I refused to do; but I took off my bonnet. The defendant then came into the room and he asked me to open my mouth. I was sitting in a chair. I went to speak to the defendant, but he cried out—"My time," and then I opened my mouth. He said: "I must have this and that tooth out." I said "No." He said: "Keep your good looks as long as you can." Mr. Byers came into the room, and without previous warning, he put the chloroform over my mouth and nose. I tried to get up, and partly succeeded as Mr. Statham was wrenching my mouth open. I became entirely unconscious. I became conscious when the defendant was taking out the fifth tooth. I fought very hard, and shrieked and tried to get up, and should have succeeded, but the defendant caught me by the throat and called out, "Give her more chloroform." They undressed me and put something over my mouth. I could not see, but could hear and feel all they were doing to me, and said, "Pray, pray don't." Mr. Byers gave me more chloroform, and Mr. Statham took out the last tooth on the other side. He took out six double teeth. When I came to myself I was in bed, and they gave me brandy and water. I was coming from death to life, and my throat was very painful. I said, "Oh, Mr. Byers." I brought up great quantities of black clotted blood. I was sent home in a cab about eight in the evening, with a little brandy. I was sick all night. I was very bad next day. I went to the hospital in the morning and saw Mr. Byers, who said I had had a very hard struggle, and he could hardly hold me. I could not hold anything in my hand. I went to the hos-

pital again the following week, as I was distracted with the pains in my head, jaw, and ears. I had no sleep. Mr. Byers said I had neuralgia. I could get no relief. Mr. Byers afterwards wished me to see Dr. Cholmeley, one of the head physicians of the hospital. I saw the defendant again in a about a month at his private house. He asked me to have refreshment, and I had some brandy and water. He was very kind to me, and said he would see any lady on my behalf. I told him of my sufferings, and that he had nearly killed me. He said he would do all he could for me. He gave me 2s. 6d. to pay for my cab. He gave me a card, upon which he wrote my name, to show at the hospital. I afterwards saw defendant and Dr. Cholmeley. Defendant told me to come to his house whenever I liked. I did go, and saw him several times. I took medicine given me by Dr. Cholmeley. I got a little better, but was still very ill; my head was cold, and my throat was in very great pain where the defendant had grasped it; it had remained ever since he did so. I feel it now upon every little cold. I afterwards saw Mr. Gant, at the Royal Free Hospital, before I went to Walton. I went to Walton-on-Thames about two months after the operation. Dr. Cholmeley got me the recommendation to the hospital there. I was very ill there. I got into St. George's Hospital. My shrieks frightened them there. I went to Walton again about January, and remained there a month; I then went to the infirmary at Margate, and was there more than three months. I got worse. I could not turn in my bed, and lost the use of my limbs. I was painted with iodine. I was taken on a stretcher to the sea. The defendant gave me £3 or £4 to go down with, and I received money from him while I was down there. I think I had £6 10s. from him. I had letters from him. (The letters were couched in kind terms, expressing a hope that she was improving, and saying he had promised to pay all expenses, some enclosing post-office orders.) The defendant procured lodgings for me for a short time. He then came and fetched me home. He took me to the London Hospital. He came to see me there. In four months defendant came and took me to the Great Northern Hospital, and I was under the house-surgeon. The porter had orders to take me home. I have been three months in St. Mary's Hospital. The defendant has frequently visited me. I have received about £20 from him. About twelve months since the defendant said he would allow me 10s. a week. I said all I wanted was my health, and £1 a week that I might be attended upon. I worked for many ladies before this occurred. I have not been able to go out since. I am entirely dependent on my labour. I have been separated from my husband sixteen years.

Cross-examined—I am thirty-four years of age. I had been under Mr. Gant as an out patient of the Royal Free Hospital. I had been at Guy's for great nervous debility. Mr. Byers examined my mouth. Three of the extracted teeth I could crack nuts with; the other three were stumps. Mr. Byers recommended me to call on the defendant, as I should be passing the street. All the attendance was gratuitous. The defendant said he could not relieve me without taking out one tooth. I said I could not endure the pain, and it was then he suggested chloroform. Dr. Kelly administered chloroform to me sixteen years ago for a poisoned finger. I never had scrofula. I believe Dr. Cruicknell examined my heart. I have been frequently requested to take chloroform, but I always resisted, and it was not pressed. Dr. Cruicknell said to Mr. Byers that he might give me a little; he did not see danger. I said I could not have a tooth taken out, as I could not bear the pain. I did not know that the room I was taken to was the operating-room. When I became conscious, I was aware some teeth had been removed, but I was in too great pain to make any complaint. On my way home in a cab after the operation, the cabman had an altercation with some man. I was much frightened, and I was taken into a house. This made me worse. I complained to Mr. Byers of my teeth having been taken out. This was the day after they were taken out. I never asked Mr. Byers to administer chloroform to me at his own house. I went to Margate for enlarged glands in my throat, and not for scrofula. I believe I was treated for hysteria. I told Mr. Byers the pain in my throat was owing to the defendant's grasping my throat, but I was thinking chiefly of my teeth. I did not complain at Margate of the violence to my throat. Mr. Statham was always very kind to me after the operation. I told him I was unable to work.

Re-examined—I was under sixteen when I was married.

Mr. F. J. Gant—I am one of the surgeons of the Free Hospital in Gray's-inn-road. The plaintiff consulted me about August, 1864. She complained of pain in her jaw and joints. I prescribed for her. Her general condition was one of extreme nervousness—starting at the slightest sound, wincing at the slightest touch; she was wild and agitated; she was exceedingly weak. I regarded her as suffering from neuralgia. I did not know what she was. After the operation she again came to me, and stated she had great pain still in her jaw, and could not sleep at night. She felt as if her head was being twisted off her shoulders. Her symptoms were worse than they were before. I think the sensation of twisting of the head might have reference to the extraction of the teeth. I did not see her walk. She urged me to give her an order for admission into the Margate Hospital, but, as she had not scrofula, I refused to do so. She complained of her throat and of her glands being enlarged, but I replied that that was not scrofula. If the teeth were decayed, their removal might be beneficial. I came to the conclusion that the pains were neuralgic. I would not advise six teeth to be extracted at one and the same time in her then state. It would be liable to affect her nerves and deprive her of sleep. I should think, mentally speaking, she is better. I have never given chloroform, but have been present when it has been given. I have seen one death only from it. To the best of my knowledge, the effect is transitory; there is sometimes great depression and debility arising from it for some days. It was right to remove the cause of irritation. I should have preferred the administration of chloroform; much depends upon the state of the patient at the time.

Re-examined—I think the administering chloroform against her will and the struggling would leave a nervous shock after the actual effect of the dose had ceased, and her debility would be increased.

Daniel Hooper, physician—I saw the plaintiff last May. She was feeble and excitable. Her limbs twitched and worked before I could feel her pulse—hysteria. I think what took place might have aggravated her condition.

Cross-examined—With regard to hysterical patients, you cannot always rely upon their statements, and that was what I considered of the plaintiff. She told me she chloroform had injured her.

Dr. Hyde Salter—I am attached to the Charing-Cross Hospital. I have no recollection of having seen the plaintiff. This is my prescription (produced by the plaintiff) for hysteria—a nervous affection. It must exist before a violent shock, which may increase it, but would not produce it. I have known persons to be thrown into hysterics by a violent shock. If a patient told me that a medical man had stated that chloroform would be dangerous, I should treat it with doubt. I am not sure that I should go and see the other doctor. If I thought the patient merely had a fear of it, I should not think it necessary to see the former medical man. I should say the administration of chloroform had nothing to do with the plaintiff's present condition. I only judge from her appearance here.

Dr. Fredk. Kelly—I have known the plaintiff from sixteen to eighteen years. Some twelve years since I administered chloroform to her for a poisoned finger. It produced severe convulsions and a hysterical attack of a very severe character. I was in a very anxious state, and I gave her father instructions that under no circumstances whatever should she again take it. A repetition of it would have an immediate risk. I have occasionally seen and prescribed for her since. Looking at her condition, I should not have administered it in 1864, on account of her highly nervous condition. Her condition has been aggravated. A shock upon the hysteria might produce lameness. I was present when the defendant offered her sixteen shillings a week until she got well. She said she could not do with less than a pound a week to maintain her and pay her rent.

Cross-examined—I was present at the interview at the request of the defendant. I have administered chloroform eight or ten times in the course of a practice of twenty-two years. It does not generally produce convulsions. There is a fear of the pulsation of the heart ceasing. I have not made it a study, and it is a matter with which I am only imperfectly acquainted. I signed a certificate for her admission into the Margate Infirmary, but I don't know that it is for scrofulous patients only. She had not scrofula. I have signed a great number of such certificates.

Nov. 13TH.

The proceedings in this case were resumed this morning. Dr. KELLY treated the plaintiff in 1865 for hysteria and debility.

Mr. Giffard then addressed the jury on behalf of the defendant. His friend had introduced the case on generalities which usually consisted of deceit. The first complaint was that of an assault in administering chloroform against her will and extracting her teeth; and secondly, that the defendant by want of skill and negligence had caused her great injury. The defendant's brother was the founder of the hospital. The plaintiff went to the hospital and saw Mr. Byers, who considered that her state arose from decayed teeth, and, finding where she lived, he recommended her to go to the defendant, who is a surgeon-dentist. He examined her, and felt that the teeth must be extracted, and as she expressed her fear of this he mentioned chloroform, and sent her to the hospital for examination, and she was aware of the purpose of her going there. Upon consultation there the medical men said chloroform could be administered with safety. She went into the room upstairs and took off her bonnet. Could she doubt that her teeth were to be extracted. She came to herself and found her teeth had been extracted. She did not then complain of it having been done against her will. There was, therefore, no opportunity for immediate contradiction of a complaint. No doubt she did not give a formal consent. A person went to a dentist for the purpose of having the teeth examined, and perhaps extracted, but no one thought of calling this an assault. When in Margate the plaintiff had written letters to the defendant couched in terms of great gratitude. The jury could hardly give credence to the statement of the inhumanity of the defendant in seizing her by the throat. Her complaint, as made by her attorney, was the administering chloroform to her against her will, and by force, and after she had informed the defendant that her former medical man had stated that the giving chloroform would endanger her life. It was then said that the defendant had not exhibited proper skill. No doubt a medical man was obliged to treat a poor patient with as much skill as a more wealthy one. Dr. Kelly had told them that fourteen years ago she was in much the same state as she was now. What particular item did this charge of want of skill refer to? Was it right to remove the teeth? The defendant, who had been long in practice, was of opinion that it was proper. Mr. Gant could give no opinion upon the subject, because he had not examined her mouth. Was it proper to extract six? Was it right to administer chloroform? Other medical men had agreed with the defendant in the whole course he had adopted. Not one of the medical witnesses who had been already called had said this administration was wrong. Dr. Kelly had made an experiment upon her fourteen years ago, but no one could tell in what quantity he had administered it, or whether it had been administered skilfully. It certainly was the first time Dr. Kelly had administered it. This imputation against the defendant was a death-blow—it was sometimes the fulcrum upon which money was extorted. Although there was not sufficient to lead to a verdict for the plaintiff, yet in such a case the imputation must not be allowed to remain uncontradicted. The defendant had in many instances relieved the sufferings of patients who had not the means of procuring comforts for themselves; but that was not to be taken as an admission of his having been guilty of a wrong. The defendant might have thought it advisable to give even a pound a week in preference to defending an action, for, whatever might be the result, some would advert to the imputation. He should call witnesses, who would assert that what the defendant had done was the proper course to be adopted. There must always be a degree of sympathy for the sufferings of a woman, such as they had witnessed yesterday, but those sufferings were not to be attributed to the conduct of the defendant. The jury should attend to the great maxim of the law, to hear both sides before they decided.

Mr. Statham—I am the defendant. I was educated at Harrow. I am one of the surgeon-dentists of the Great Northern Hospital, which was founded by my brother. The plaintiff called upon me in 1864 relative to some neuralgic pains in her head. I gave her some anodyne to be applied to her gums, and desired her to let me see her again in a few days. I considered that the pains were attributable to her teeth, and I told her that she should have them cut. I

saw her again in a day or two afterwards, I imagine, at the hospital. I suggested to take out one tooth, and I mentioned chloroform to her. She said she could not bear the pain of extraction. She said chloroform had been administered to her many years ago by her medical attendant, and the effect had been to produce alarming symptoms, which I considered to be hysterical mania. She said she could not take chloroform. I desired her immediately to see her medical attendant, and the answer was, she did not see him now. I still advised her to see him, and I did so again on her next visit, and she said she considered the advice of Mr. Byers and my own sufficient. After several visits an appointment was made for her to go to the hospital on the ensuing Wednesday, the operation day (the 17th of August). She clearly understood she was to take chloroform, I told her it was necessary the teeth should be taken out in order to relieve her. I have no doubt I told her how many teeth. I had formed a judgment as to five or six. I removed six. She was examined at the hospital by Dr. Cruicknell, who said she was fit for chloroform. I cannot recollect whether she made a reply, but I think it was a word like "Yes." I believe I proceeded to the operating-room. She never loosened her dress. She made no sort of resistance or objection. Mr. Byers administered the chloroform and I extracted the teeth. It was admirably applied. She became conscious at the time I was taking out the fifth tooth. I deny taking her by the throat. It would not have been proper to defer the operation, as she was only half conscious. I would not have undertaken the operation except under chloroform. It required more than usual care and skill. I preserved the teeth. They were larger under the jaw than above. They were the cause of the nervous pain in the jaw, and it was absolutely necessary to remove them. She was put to bed, where she remained until the effect had left her. She then said the chloroform had killed her. She did not say it had been done without her consent. Hysterical patients require care, and they often make complaints and talk wildly. I saw her again in three weeks, when she demanded compensation for the injurious effects of the chloroform. I denied the injurious effects, and referred her to my solicitor if she intended to proceed; but as a matter of kindness, of charity, and good feeling, I said I would do what I could for her. She said it would not be necessary to proceed if she could get a little help and assistance for the time being. I did assist her with money from time to time, as I had promised her.

Cross-examined—I have not a perfect recollection of anything that took place prior to the operation. I referred her to my solicitors by name, one of whom was my cousin, who afterwards handed over the case to Humphreys and Morgan. I have been dentist to the hospital since 1856. I am a Dental Licentiate of the College of Surgeons. I have extracted many thousands of teeth, delicate and difficult. We only keep teeth, by permission of the patient. I had her permission after it was done, after she had demanded compensation. I have no doubt I consulted my cousin about three weeks after she made the demand for compensation. Meanwhile I was seeing her from time to time. She never mentioned compensation again. She might have told me that her medical man had told her father that it was dangerous for her to take chloroform. I did not think it necessary to see the medical man, but it is advisable. I think she said it produced hysterics—nervous debility, and that she was almost out of her mind; that she went to St. Bartholomew's afterwards. I believe she gave me the name of Dr. Kelly. I don't recollect her giving me his address. I am afraid it is not the practice to write to a medical man to ask him the question, I told her to go to him, and, therefore, I did not think it right to trouble Dr. Kelly. She was one of the most nervous patients I ever saw, and I thought it my duty to reassure her as much as I could. She stated that she had been sent to me by Mr. Byers. That was about a month before the operation. I told Dr. Cruicknell what she had stated her former medical man had said, but I told him I thought she was a fit subject for it, and I did not think it would do her any harm. He examined her with the stethoscope. Hysteria may be converted into hysterical mania by violence. She struggled slightly when under chloroform. She shrieked when she partially recovered. I did not prevent it. Mr. Byers administered more chloroform, I believe. I am not aware that he said her pulse was failing. I might have said, "Never mind her pulse, her breathing is right." Probably the operation was

occupied twenty minutes altogether. I held her down when she attempted to rise. I did not place great faith in her statement about the prior effects of chloroform upon her. I did not treat her as being under a delusion. I went to Margate when she was there. I fetched her up and took her to her old lodgings.

Mr. Byers—I was acting house-surgeon to the Great Northern Hospital in 1864. I examined the plaintiff's mouth, and recommended her to go to the defendant. She afterwards came and told me that Mr. Statham had recommended the extraction of some stumps, and for her to take chloroform. She made no objection. On the evening before the operation she called to me and asked me to administer chloroform. I told her before that could be done she must be examined by the physician. She was examined by Dr. Crucknell. He said there was no danger in her having chloroform. I told her to go upstairs and wait, and I directed the porter to send up a nurse and one of the sisters. I afterwards went up and administered chloroform in the usual way. I did not see defendant grasp her by the throat. The extraction of the teeth was very well performed. She never told me that it was done against her will.

Cross-examined—I have been in the profession twenty years, but am not a surgeon. I have not undergone any examination, except at Apothecaries' Hall. I am now assisting a gentleman at Market Harborough. I was called upon to refresh my memory with regard to this matter about three months since. I took her case to be one of debility—highly nervous hysteria. She never told me about the effects of chloroform upon her on a former occasion.

Dr. Crucknell, Physician at the Great Northern Hospital in 1864—I have only been a practitioner four years. I am unable to recollect anything respecting this particular case. I frequently examined patients before they underwent chloroform. I saw the plaintiff here yesterday. It is extremely unlikely for there being any connection between her present state and the administration of chloroform in 1864.

Dr. Anstie, Assistant-Physician at Westminster Hospital—For some time I devoted my attention to chloroform. I have administered it to more than 6000 persons. It is very volatile, and leaves the patient with great rapidity. It is impossible that the condition of the plaintiff, as I saw her yesterday, could have had anything to do with the administration of chloroform. The inflammation produced by the decayed teeth would be very injurious to her. It was specially necessary to give chloroform, looking at all the circumstances of the case. Probably it was much better to take out the whole six teeth at one than two sittings. If a patient should hold her breath for two or three minutes and then there should be a sudden respiration, a large dose might be drawn in and prove fatal. From all I have heard I should say she was a fit subject for chloroform.

Dr. Sansom, of University College—Had ten years' experience in the practice of the administration of chloroform. It was utterly and absolutely impossible to connect the present state of the plaintiff with the administration of chloroform. The effect would remain but a short time.

Dr. Richardson, Consulting Physician to the National Dental Hospital—I have examined these six teeth. (The witness described the state of the teeth.) They would have produced more intense pain than any disease of teeth with which I am acquainted. It was proper to remove them under the influence of chloroform. From my experience, I prefer finishing the operation at one sitting.

The cases of both the plaintiff and defendant having been concluded, and it being now nearly four o'clock, the jury were asked whether they would wish the whole matter to be concluded this evening or adjourned till to-morrow. The jury expressed a wish that it should be concluded to-night.

The learned counsel then proceeded to address the jury for their respective clients.

Mr. Justice BLACKBURN summed up.

The jury retired, and after an absence of some hours, at half-past eight o'clock, said there was not the slightest chance of their agreeing to a verdict. At twelve o'clock, not having agreed to a verdict, they were discharged.

LADY PALMERSTON and some benevolent ladies and gentlemen are about to build a small hospital at Romsey, in Hants.

DUBLIN CORPORATION.

PROCEEDINGS OF THE TOWN COUNCIL.

HOSPITALS.

On section No. 4, allowances to hospitals, £1870, being considered,

Mr. Justice George said he found under this head a new presentment of £300 to St. Vincent's Hospital. According to the provisions of the Acts of Parliament respecting such matters, votes of money from the public funds should be proportioned to the amount of private subscriptions. He wished to know whether in this case the private subscriptions were in excess of the proposed grant?

Alderman Tarpey—Yes, my lord, by £208.

Mr. Justice George—I wanted that to be known; I will fiat the presentment.

CORONERS AND MEDICAL WITNESSES.

The presentment for coroners' medical witnesses, and other expenses of inquests, was for £368 14s. 3d.

Dr. White, one of the coroners, called attention to a letter which had been received by him from the Town Clerk, stating that the Council had taken legal opinion as to the cost of medical witnesses, and they were advised that the coroner was only allowed to call in one witness, who was to be paid a fee of one guinea, or in the case of a post-mortem examination of two guineas. The Act of Parliament expressly provided that where the jury desired it a second medical witness should be called in. He had applied for a copy of the case and opinion of Mr. Dowse, but had been refused. If the opinion was as the Town Clerk represented it, it either grossly misrepresented Mr. Dowse or was contrary to law (laughter).

Mr. Dowse—Provided you do not hold an inquest upon me I do not care (laughter).

Dr. White—That is the very last service I would do for you (laughter).

Mr. Dowse—I advised that the coroner had only authority to call in one medical witness, except in the event of the jury stating that they would desire further medical evidence.

Mr. Justice George—Do you object to the presentment for salary?

Dr. White—No.

Mr. Purcell, Q.C., said he appeared for Dr. Kirwan, the other coroner, who had discharged the duties of the office for twenty-three years, and held between 300 and 400 inquests annually, to complain that without notice to him the Council had reduced his salary by one-half. The learned counsel contended that the Dublin Improvement Act having provided for the presentments being brought before the court for its fiat only once every year, and the Coroners' Act expressly providing that the fees should not exceed £65 in each half year, it was ridiculous to suppose that the presentment was to be but that amount for a whole year.

Mr. Dowse, Q.C., said the Council had no desire to do anything which would injuriously affect either Dr. White or Dr. Kirwan, but they had a perfect right to raise the question, having been advised that it was not competent for them to present a larger sum in any presenting term than £65 for each coroner.

Mr. Justice George said the question had been properly brought before him. His view of the law coincided with that held by Mr. Purcell. He could not conceive that the Legislature would, without express enactment, reduce the salaries of the coroners, and he could not hold that because the presenting term of the Municipal Council was now only once yearly, they were restricted to a presentment which would only cover a period of half a year. Under the circumstances he would direct the presentment for salaries of coroners to be amended by being increased from £130 to £260.

Alderman Reynolds said he wished to explain that this

Medical News.

case would never have come before the Court were it not for a difference between the Council and one of the coroners. One of the coroners claimed the privilege of summoning as many doctors as he wished to give evidence. The Corporation had witnessed the increase of the charges on the grand jury cess with alarm. They found they were paying about £600 a year for medical witnesses—a duty which they used to get discharged for from £100 to £150 a year. The Council claimed the privilege of employing a medical officer at a permanent salary. They would get probably as competent a man as any in Dublin, Dr. Mapother, to do the whole duty for £150. Dr. Kirwan would agree to this, but Mr. White would not agree to it, and claimed the privilege of employing as many medical witnesses as he thought proper. They wished to put an end to this. For his part he would not object to pay each of the coroners £130 a year, provided they would agree to the equitable arrangement of relieving the Council from the enormous sum of £600 a year. It was a very disadvantageous power to leave in the hands of the coroner, that he might employ as many medical witnesses as he pleased. Unless it was agreed to allow the Corporation to employ the medical officer he thought he would, though very reluctantly, appeal against the decision of his lordship.

Mr. Dennehy, T.C., said that, until the last four years, the system advocated by Alderman Reynolds had been carried out. The medical man, who had been employed at a salary of £160 a year, had resigned, and the coroner refused to allow the system which had been working well for so many years to be continued.

Mr. Justice George said there was no matter before him for decision. According to the 28th section of the Act of Parliament, one medical witness only could be summoned by the coroner, and it was only under the provisions of the 34th section that the jury could require to have another. It was the bounden duty of the coroner to take care that the proceedings were properly carried out. The Court of Queen's Bench could remedy any abuse of the coroner, and make him perform his duty. He (the learned Judge) would be sorry that a gentleman holding one of the most responsible offices under the constitution would lend himself to anything of the nature suggested. It certainly was a matter of observation that in some shape or other these expenses for medical witnesses had amounted from £150 a year to £600.

Dr. White—The figures are only £200 for all the witnesses, and I never offered against the Act, or availed myself of the 34th section.

Mr. Purcell mentioned that the coroner had no legal power to appoint a medical man.

Mr. Justice George—He is entitled to call in one medical witness under the 20th section, and if the jury are not satisfied they can, under the 34th section, call in another.

Alderman Reynolds—I do not mean to insinuate that the coroner has any legal power in the matter, but he stands as an obstacle in his own way of appointing a permanent medical officer.

Mr. Justice George—The coroner ought not to have any interest one way or another in the matter.

Alderman Reynolds—Whether he has or not he has exercised an indirect power.

Councillor Dennehy—It would set the question at rest if the coroners would promise to do what is desired of them.

Mr. Purcell—If the coroners take my advice they will hold their tongues (laughter).

The French Minister of the Interior announces that a prize of 1500 francs will be given, in 1847, to the author of the best work on Archæology; and that another prize of the same amount will be given for the best essay on the Commerce and Industry of the Middle Ages, derived from authentic documents, referring either to a province or to a town, with reference especially to the practices and rules of trades, the condition of workmen, employers, customers, &c.

APOTHECARIES' HALL OF LONDON.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise on Nov. 15th:—

Thomas, John Davies, Bryn Villa, Swansea.
Tidswell, Thomas Harrison, Spalding, Lincolnshire.

The following gentlemen also on the same day passed their first examination:—

Walter Wm. Inglis, St. Thomas's Hospital; Alex. Fox, London Hospital.

UNIVERSITY INTELLIGENCE.—UNIVERSITY OF LONDON.—The following is a list of candidates who passed the recent Second M.B. Examination:—

Pass Examination.

First Division.—Francis Bateman, St. Bartholomew's Hospital; Francis John Buckell, University College; Stephen Wootton Rushell, B.Sc., Guy's Hospital; Henry Clothier, University College; Thomas Cole, St. Bartholomew's Hospital; George Eastes, Guy's Hospital; John Spencer Ferris, King's College; Ralph Gooding, B.A., King's College; Henry Greenway Howse, Guy's Hospital; John Pearson Hughes, University College; Chas. Kelly, King's College; Frederic Barham Nunneley, University College; Charles William Philpot, B.Sc., King's College; Thomas Clay Shaw, B.A., King's College; George Othwaite Spencer, University College; John Kent Spender, King's College; George Christopher Taylor, St. Bartholomew's Hospital; Arthur Taylor, Guy's Hospital; Richard Thorne Thorne, St. Bartholomew's Hospital; John Burges Welch, King's College; John Williams, University College.

Second Division.—John Augustus Ball, Guy's Hospital; Clement Smith Barter, St. Bartholomew's Hospital; Julian Augustus Michael Evans, University College; John Grimes, B.Sc., King's College.

THE urgent appeal for assistance to a destitute medical brother which appears in our columns to-day is one which we know to be well founded. The gentleman who is its object has been reduced, without any fault of his own, to absolute penury, and has sacrificed to the last his comforts to the honourable discharge of his engagements. We cannot conceive a case more dependent or demanding more the sympathy of his profession, and we shall be glad to be permitted to add to the list the name of any of our subscribers, and to place the amount of any donation against their debit in our books, on receiving their authority to do so. We have pleasure in inscribing the Editor of THE MEDICAL PRESS AND CIRCULAR for a subscription of one guinea.

THE long and valuable services of Dr. Purcell as Inspector under the Poor-law have received a due recognition in the Testimonial for which subscription is now being made. The list of subscribers will be found in our columns to-day and in a late impression, and the names which there appear are an eloquent testimony to the justice and urbanity with which Dr. Purcell's duties have been discharged. The Poor-law Medical Officers have lost much in the withdrawal of Dr. Purcell, and we shall be glad to hear that an old friend and a valuable public servant has been honoured as he deserves to be.

THE FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The examination for this distinction took place on Tuesday, Wednesday, and Thursday last, at the College of Surgeons, when twelve candidates presented themselves—viz., six seniors and six juniors. It is not, perhaps, generally known that under recent regulations candidates may offer themselves on two occasions, instead of one, as heretofore; for instance, the examinations in anatomy and physiology, with dissections, may be gone through, say in November, and those on pathology and surgery, with operations, in the following May. The list of successful candidates will not be known until next week.

COLOUR OF THE SKY AT SUNRISE AND SUNSET.—The invention of spectrum analysis is daily receiving wider extension, and by Janssen has just been applied to meteorological researches. This investigator was led, from some observations made on the Faulhorn, to believe watery vapour had something to do with the absorption of solar rays in

passing through the atmosphere. More exact research subsequently showed that aqueous vapour had the power of absorbing certain red and yellow rays, but is very transparent for the majority of these. From this it follows that aqueous vapour, when seen by transmitted light, should possess an orange colour, and the thicker or denser the layer of this, the redder the colour assumed by it. Now, it is just when the sun's rays are passing through the dense layer of vapour which surrounds the earth—that is, when the sun is rising or setting—that the red colour is observed; and in the explanation given above we have probably the key to the phenomenon.

WHAT IS ROTHEN?—In an article in the November number of the *Edinburgh Medical Journal*, Dr. Veale, of the Royal Artillery, describes what he has seen in India of the above disease. This appears to be a sort of compound of measles and scarlatina, and is sometimes termed rubeola rotha. There is the eruption and coryza of measles, and the inflamed tonsils and submaxillaries of scarlatina, with occasional stomacheic disturbance before the appearance of the eruption; the kidneys do not, however, seem to be subsequently affected. Dr. Veale believes that the disease is due to a specific morbid poison similar to those which produce the other eruptive fevers.

SCOTTISH REGISTRAR-GENERAL'S RETURN.—The return last issued for the third quarter of the present year records 5,451 deaths in Scotland in that quarter, being in the annual proportion of 195 deaths in every 10,000 persons of the estimated population—232 in the town districts, and 153 in the rural. This is a lower ratio of mortality than in the third quarter of either of the previous three years, but is above the average if we take the last ten years, as they give only 178. This increased mortality was chiefly to be attributed to the presence of scarlatina and whooping-cough among children. Typhus and typhoid fevers, which had been prevalent during the previous quarters, seemed to be most everywhere abating. Epidemic cholera, however, made its appearance in Scotland the last week of July, and though its ravages, when the quarter closed, had been partial, and the deaths comparatively few, they sensibly augmented the mortality of the quarter. The disease seemed to have invaded Scotland much in the same manner as in 1848, appearing first in the seaboard towns and villages on the east coast, and then spreading over the country, principally selecting as its victims the inhabitants of the town, village, street, or hamlet who were living in a locality in a bad sanitary condition, or who were using water from rivers, burns, ditches, pump-wells, or cisterns whose purity had been more or less affected by containing organic matters in a state of decomposition. It is mentioned that the microscope often detects the presence of these organic matters when chemical analysis fails to show that anything is wrong. In 1832 epidemic cholera broke out in Scotland towards the end of January, and then followed the law which seems to regulate its progress in all the warmer countries of the Continent—viz., increased with the rise of temperature, proved most fatal in the autumnal months, and died out in December. In its subsequent attacks, however, it followed in Scotland a different law—the law which seems to regulate the spread of fever, and most epidemics there—viz., it first manifested itself in the autumn, as the weather began to cool, increased with the fall of temperature, and died out in the spring on the advent of the warm weather. It would be very unwise for the Scotch to assume that the cold weather will now arrest its course, and neglect to employ the sanitary means which have been proved materially to check its ravages. The births in Scotland in the quarter were 27,197, being in the annual proportion of 345 to every 10,000 persons of the estimated population (374 in the town districts, 312 in the rural), the average being only 336. Ten per cent. of the children born were illegitimate. The marriages (889 in number) were in the annual proportion of 11 in every 10,000 persons (84 in the town districts, 26 in the rural), the average being 60. The weather in Scotland during the quarter was colder, more rainy, more cloudy, and the atmosphere damper than it has been for many seasons; fogs and mists prevailed to an unusual extent; there was much less sunshine than in ordinary seasons—in August and September only 279 hours, taking the mean of 55 stations—that is to say, 63 below the average; and the daily variations of temperature, particularly during

the latter half of September, were much less than usual. The return notices that the connexion of such weather with increased mortality is not very apparent; but that it is a remarkable fact that the description published in 1848 relative to the kind of weather which prevailed previous to the outbreak of cholera in Scotland during that year might be substituted for that which prevailed previous to its outbreak this year; and the same kind of fog, which wind does not seem to remove, has hung over the country, and more especially over the towns and villages affected with that epidemic. The mean temperature of the quarter was 54.4 deg.; in the corresponding quarter of last year it was 57.5 deg. The rainfall of the quarter amounted this year to 11.47 inches.

PROF. AGASSIZ has been delivering lectures in the United States on the physical features of the river Amazon, which he has lately investigated at the expense of Mr. Thayer. The Professor states that there is no difficulty whatever in navigating the Amazon and all its tributaries with steamers. The climate he describes as delightful. The nights are cool, because the Amazon runs from west to east, in the face of the trade-winds, so that cool breezes are continually blowing up the river; and the steamers of the Amazon Steam-Ship Company are so comfortable and well managed, that a trip to the foot of the Andes in them is, according to the Professor's experience, as agreeable as an excursion on the Rhine.

Appointments.

LONDON.

- FOX, CHARLES JAMES, M.R.C.S., has been elected Assistant L.D.S., Dental Surgeon to the Dental Hospital of London, Soho-square, vice Mr. J. Walker, M.R.C.S. and L.D.S., resigned.
- BRANSON, H. J., M.R.C.P. Ed., has been elected a Fellow of the Obstetrical Society of London.
- DRYSDALE, C. E., M.D., has been appointed Assistant-Physician to the Metropolitan Free Hospital, Devonshire-square, vice W. Abbotts Smith, M.D., resigned.
- RANDALL, J. G., M.R.C.S., has been appointed House-Surgeon to the Female Lock Hospital and Asylum, Westbourne-green, Harrow-road.
- SQUAREY, C. G., M.R.C.S.E., Resident Medical Officer to the London Fever Hospital, has been elected Resident Medical Officer to University College Hospital, vice Walter Rickards, M.D., resigned.

SCOTLAND.

- DUNCAN, A., M.B., has been appointed a Medical Officer to the Aberdeen Dispensary.
- FRASER, A., M.D., has been appointed a Medical Officer to the Aberdeen Dispensary.
- MILLAR, Dr. has been appointed Medical Officer to the Coltness Iron Works, Wishaw, Lanarkshire, vice J. McNab, M.D., resigned.

PROVINCIAL.

- DRUMMOND, Mr. A., has been appointed Resident Surgeon-Accoucheur to the Birmingham General Dispensary.
- FRYER, Dr., has been appointed Assistant House-Surgeon to St. Mary's Hospital, Manchester.
- LOYD, R. R., M.R.C.S.E., has been appointed House-Surgeon to the Peterborough Infirmary.
- NANKIVELL, A. W., F.R.C.S.E., L.R.C.P. Lond., has been appointed House-Surgeon to St. Bartholomew's Hospital, Chatham.
- RICHARDS, J. P., M.R.C.S.E., has been appointed Assistant Medical Officer to the Devon County Hospital.
- THORRURN, J., M.D., has been appointed Lecturer on Midwifery and Diseases of Women and Children at the Manchester Royal School of Medicine and Surgery.
- ATKINSON, Dr. F. P., has been appointed Visiting Surgeon for Chatham under the Contagious Diseases Prevention Act, 1836.
- BLADEN, R., L.R.C.P.L., has been appointed Medical Officer for District No. 4 of the Stroud Union, Gloucestershire, vice Rowe, resigned.
- CARTER, A. P., M.R.C.S.E., has been appointed Surgeon to the Great Western Railway Company in the Gloucester District, vice A. Clarke, M.R.C.S.E., deceased.
- ELLISON, J., M.D., has been appointed joint Surgeon and Apothecary to her Majesty's Household at Windsor, vice H. Brown, M.R.C.S.E., resigned.
- FAIRBANK, T., M.B., has been appointed joint Surgeon and Apothecary to her Majesty's Household at Windsor, vice H. Brown, M.R.C.S.E., resigned.
- READ, Dr. R., has been elected Medical Officer and Public Vaccinator for the Tealby District of the Caistor Union, Lincolnshire, vice J. Locking, M.D., resigned.
- TURTLE, F., M.D., has been elected Medical Officer and Public Vaccinator for the Woodford District of the West Ham Union, Essex, vice R. Duchesne, M.D., deceased.
- WANE, W., M.R.C.S.E., has been appointed House-Surgeon to the Stockport Infirmary, vice J. P. Richards, M.R.C.S.E., resigned.
- WATMOUGH, Wm., M.R.C.S.E., has been appointed Medical Officer for the Eastern District of the Christchurch Union, vice R. S. J. Stevens, M.D., resigned.

WINSTANLEY, R., M.R.C.S.E., has been appointed Medical Officer for the West District and the Workhouse of the Wigan Union, Lancashire, vice J. T. Winnard, M.R.C.S.E., resigned.
 KELSEY, A., M.R.C.S.E., has been appointed Surgeon to the Redhill Infirmary, and Medical Officer and Public Vaccinator for the Northern District and the Infirmary of the Workhouse of the Reigate Union, Surrey, vice W. T. Sargent, M.R.C.S.E., deceased.

IRELAND.

REA, S., L.F.P. & S.Glas., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births, &c., for the No. 5 Belfast Dispensary District of the Belfast Union, vice J. H. Halliday, M.D., deceased.
 TUSCH, J. G. L.K.Q.C.P.I., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births, &c., for the Blarney Dispensary District of the Cork Union, vice M. J. Lee, L.R.C.S.Ed., deceased.
 MOOREHEAD, Dr. R., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births, &c., for the Articlave Dispensary District of the Coleraine Union, county Londonderry, vice J. W. Wolfenden, L.R.C.P.Ed.
 LESLIE, J., L.K.Q.C.P.I., has been appointed Medical Visitor in Lunacy to the High Court of Chancery in Ireland for the county Armagh.
 ARCHDALE, H. M. G., L.R.C.P.Ed., has been elected Medical Officer, Public Vaccinator, and Registrar of Births, &c., for the Quin Dispensary District of the Tulla Union, county Clarge, vice C. J. Healy, L.R.C.S.I., deceased.
 ROUGHAN, G. F., L.K.Q.C.P.I., has been appointed Medical Poor-law Inspector, Ireland, vice J. F. Purcell, F.R.C.S.I.
 McDONNELL, ROBERT, M.D., F.R.S., F.R.C.S.I., has been elected one of the Surgeons to Stevens' Hospital, Dublin, in the room of the late Mr. Symes.
 DAVIS, G. M.B., M.D., has been appointed Apothecary and Registrar to the Monaghan County Infirmary, vice Corbett, resigned.

PALK.—On the 14th inst., at Sussex-place, Southampton, the wife of Henry Palk, M.D., of a son.
 CARDELL.—On the 15th inst., at Salisbury, the wife of J. M. Cardell, F.R.C.S.E., of a son.
 PIKE.—On the 17th inst., at Weyhill, the wife of T. Pike, M.D., of a son.
 CARTER.—On the 18th inst., at Elizabeth-street, Liverpool, the wife of Wm. Carter, M.B., of a son.

MARRIAGES.

DAVIDSON—BROWN.—On November 15, at Kingsley Haas, W. A. Davidson, M.D., Surgeon 65th Regiment, to Anne Emily, only daughter of the late G. Brown, Esq.
 SMITH—THISTLE.—On November 14, at the parish church, Whitley, J. W. Smith, M.R.C.S.E., L.R.C.P., of Coxwold, to Martha Anne, eldest daughter of T. Thistle, Esq., of Whitley, Yorkshire.
 STUART—FRUSHARD.—On the 6th inst., at Woolston, John Stuart, L.R.C.S.I., Assistant-Surgeon 1st Batt. 8th Regiment, to Sarah Frances Frushard, daughter of P. Hedger, Esq.

DEATHS.

FOWEL.—On the 29th ult., at Milverton, Somerset, Samuel Fowel, M.R.C.S.E., L.S.A., aged 48, deeply lamented by a large circle of friends.
 CLARKE.—On the 14th inst., E. Clarke, M.D., of Scarborough, aged 32.
 RANN.—On the 19th inst., G. Rann, L.S.A.L., of Birmingham, aged 46.
 SARGENT.—On the 16th ult., by accidentally shooting himself, W. T. Sargent, M.R.C.S.E., of Redhill.
 WATSON.—On the 20th ult., at Jersey, S. K. Watson, M.R.C.S.E., L.D.S.

SCOTLAND—BIRTHS.

DAVIDSON.—On November 19, at 28, Stafford-street, Edinburgh, the wife of Dr. R. H. Davidson, of Culross-park, Deputy-Inspector of Hospitals, Bombay Army, of a daughter.
 PICKTHORN.—On November 19, at Aberdeen, the wife of T. R. Pickthorn, Esq., Staff-Surgeon H.M.S. *Saturn*, of a daughter.

DEATHS.

ROBERTSON.—On November 11, at Argyle-street, Rothesay, John Robertson, M.D.
 YOUNG.—On the 27th ult., J. Young, M.D., of Wellington-square, Ayr, late of the 48th Regiment.

IRELAND—BIRTH.

DOMENICETTI.—On the 17th inst., at Kilkenny, the wife of R. Domenicetti, M.D., 75th Regiment, of a son.

MARRIAGE.

BROWN—THOMPSON.—On the 14th inst., at Belfast, Henry Brown, L.R.C.P.Ed., L.R.C.S.Ed., of Belfast, to Jeannie, younger daughter of the late James Thompson, Esq., of Saintfield.

DEATHS.

JAMES.—On October 29, at Balcastle, Arthur James, L.R.C.S., Edin.
 KENNEDY.—On the 4th ult., at Annah House, County Tipperary, T. J. Kennedy, Staff Assistant-Surgeon, aged 32.
 LOANE.—On the 30th ult., at Kilcroy, Drumsna, J. Loane, M.R.C.S.E., aged 26.

POOR-LAW VACANCIES—ENGLAND.

Amptill Union.—Cranweid District; area 7671; population 2861; salary £50 per annum.
Banbury Union.—Hornton District; area 9740; population 3032; salary £61 8s. per annum.
Cerne Union.—Western District; area 17,634; population 3216; salary £70 per annum.

Medical Diary of the Week.

WEDNESDAY.—Hunterian, 8.—“On Scurvey in the Mercantile M a rin Dr. W. Dickson.
 — Society for the Encouragement of Arts, Manufactures, and Commerce, 8.—“On the Effect of Unlimited Liability Partnership on the Progress of Arts, Manufactures and Commerce,” Mr. Wm. Hawes.
 — Literature, 8½.—“Greek Inscription from Mitylene,” Mr. Newton.
 — Meteorological, 8.
 — Society of Arts, 8.
 — Geological, 8.—“Marine Deposits of Secondary Age, S. Wales,” “Echinodermata, Sinai,” Dr. Duncan; “Limuloideu,” Mr. Woodward; “First Cataract, Upper Egypt,” Mr. Hawkshaw.
 THURSDAY.—Mathematical, 8.—“Harmonies in Space,” Mr. Clifford.
 — Zoological, 4. General.—S. Scientific. “Inia,” Mr. Flower; “Fishes of Central America,” Dr. Gunther.
 — Royal, 8½.
 — Antiquaries, 8½.
 SATURDAY.—Botanic, 3½.

Notices to Correspondents.

Dr. Francis M. Luther.—At present we are unable to accept the services mentioned in yours of last week. If at any future time we are “open” in that department, we will not forget the translation from the “Journal de Medicine et de Chirurgie Pratiques.”

Dr. Ryan, Tipperary.—We must remind you that it is not we who imported the religious element into the matter, but those who made it the ground for a medical appointment. We did not approve of the style of the letter of M.D.; but our columns must be open to all shades of opinion.

Births, Deaths, and Marriages.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

LONDON—BIRTHS.

EASTON.—On November 16, at 20, Connaught-square, the wife of W. J. Easton, M.D., of a daughter.
 WILBE.—On November 14, at 24, Queen's-road, St. John's-wood, the wife of R. H. Wilbe, M.D., of a son.
 HENSLEY.—On the 12th inst., at Spring-gardens, the wife of F. J. Hensley, M.D., of a daughter.
 BURRELL.—On the 17th inst., the wife of L. C. Burrell, M.D., of the Green-lanes, Stoke Newington, of a son.

PROVINCIAL.

EARLE.—On November 4, at Weston-super-Mare, the wife of E. Earle, M.R.C.S.E., of a son.
 FRODSHAM.—On November 19, at the Chestnuts, Streatham, the wife of J. M. Frodsam, M.D., of a son, stillborn.
 HOLMAN.—On November 20, at the Royal Dockyard, Devonport, the wife of J. R. Holman, M.D., of a daughter.
 OWEN.—On November 12, at Totnes, the wife of T. E. Owen, M.R.C.S.E., L.S.A., of a son.
 POOLE.—On the 7th inst., the wife of S. W. Poole, M.D., of St. Paul's Cray, Kent, of a son.

"SALUS POPULI SUPREMA LEX."

INTRODUCTORY LECTURE,

DELIVERED IN THE

CITY OF DUBLIN HOSPITAL.

By Dr. BENSON,

PROFESSOR OF PRACTICAL MEDICINE, ROYAL COLLEGE OF SURGEONS.

GENTLEMEN,—It becomes my duty this year, in the order of rotation, and in accordance with established usage, to deliver the Introductory Lecture at the commencement of the Hospital Session. The Medical Officers of this institution undertake this task, each in his turn, and thus bear an equal share in the responsibility attached to it, while they enjoy equally the privilege it affords of expressing their sentiments upon any subject connected with the profession which may appear to them of importance.

I make use, advisedly, of the words *responsibility* and *privilege*. I think the person who delivers an Introductory Lecture to a class of medical students, holds a very responsible position. Many of his hearers are young and inexperienced. Some have only just escaped from the discipline of school, or have lost, for the first time, the genial influences of home, becoming their own masters amid the temptations of a great city. Surely the man who has to address to such persons the first lecture, perhaps, that they ever heard, on what is to be henceforth the business of their lives, must feel a weighty responsibility; while, at the same time, he rejoices, though with trembling, at the privilege he possesses. Students look to his age and experience for sound advice, and receive what he says, at such a time and in such a place, with respect and attention. They say, "Days should speak, and the multitude of years should teach wisdom;" and he must be conscious that an erroneous sentiment expressed, or a false principle advanced, might do serious mischief; while a word fitly spoken may do much to influence the conduct of some ingenuous youth, and to form his character. It is a pleasing task "to pour the fresh instruction o'er the mind," and to try "to fix the generous purpose in the glowing breast;" but it has its responsibilities as well as its privileges.

I propose on this occasion, as on former ones, in the first place, to make some observations on the profession which you have chosen; next, to offer some advice as to the mode of acquiring it; and then to state what helps we can afford you in this hospital.

I wish it to be understood, in adopting this course, that I am lecturing to students, and especially to juniors—not so much to senior pupils, who may have heard the admirable addresses delivered by my colleagues in former years in this place, and not at all to practitioners, though some of the latter, and some Governors of the Hospital, have honoured me with their presence. I am glad to see them, and feel complimented by their giving me their countenance, but they do not come to be lectured. It is to beginners I would chiefly address myself; and for their sakes others must kindly bear with me if they hear only what they know already—what will appear to them trite and common-place, or what they may have often heard before.

Young gentlemen, I welcome you to the profession. But let me tell you, at the threshold, that you have chosen a very anxious and arduous one—a profession that will task to the uttermost all your energies, if you would excel in it—one that will try your moral courage, your perseverance, your temper, and your patience; and these not only

during your pupilage, but all through life. You must be earnest, laborious, self-denying, and untrifling, as long as you practise your profession. Are you prepared for all this? Have you counted the cost? I would not discourage you: on the contrary, I approve of your choice. One of my own sons has chosen this profession, with my entire approval. But I would have you weigh well its advantages and disadvantages, that you may not hereafter be disappointed; that you may value it for what is valuable in it, and boldly meet, with zeal and determination, whatever is disagreeable in it. You are choosing, then, I repeat, a very arduous profession—I might almost say, a life of toil and anxiety, mingled, however, with many and exquisite enjoyments. Other professions lead to higher rank, and frequently to greater riches. There are no grand prizes to be drawn in this; no peerages in prospect, no seats on woolsacks, no ermine or lawn sleeves, or large pensions. Our profession, therefore, does not attract the aristocracy of birth, nor the worshippers of wealth; but it does attract and develop much of the aristocracy of intellect. The lovers of science find its studies congenial to their tastes, and the benevolent can here find ample opportunities for the exercise of their best aspirations. Its pursuits are ennobling and elevating to the mind; the most fascinating studies form a part of the preparation for it; while its object, end, and aim are to take from the misery and add to the happiness of mankind. I am content to place one study before it in dignity and importance, and only one—namely, divinity. The subjects which engage the attention in divinity are higher, the interests involved are more momentous. But next to that I would place the study of medicine. Other professions have, indeed, their charms and their usefulness, and I have already allowed that they more frequently lead to riches and honors; but are the objects which occupy the attention in them of such paramount importance? They have to do with property; our profession with life. They with the outworks; ours with the citadel. What is it which confessedly, even to a proverb, is the greatest of earthly blessings? What is that without which all others are valueless? Is it not health? A sound mind in a sound body. It is related of Dr. Radcliffe, whose name is immortalized by the library in Oxford, that when King William III. asked his opinion about his dropsical legs, he replied, "I would not have your Majesty's two legs for your three kingdoms." This speech was rude and offensive to ears polite, and especially to royal ears. I do not wish you to imitate it when you meet with such a case, but I mention it to show the estimate he set upon health; and it is just, perhaps, what we all would think, though not express in such pointed language. How gladly would we give all that we possess for life and health if these cannot be obtained on any other terms. Your business, my young friends, will be to preserve that life and to restore that invaluable health. The lawyer's profession is a noble one; but it is in many respects less so than ours. He has chiefly to deal with property; we with the more important concern, life. He may establish the right, protect the weak, and defend the innocent; but how often is he engaged in establishing the wrong, or screening the guilty. Go to the courts of law and you will see with what zeal and eloquence both sides of every case are maintained. One of these cases must, in general, be wrong, and sometimes the advocate might know it, if he would. But he labours to succeed, not looking too narrowly into the weakness of his own case, but seeking a triumph over his adversary. I do not, of course, mean to say that every lawyer acts in this way; the uncertainty of the law will make its most accomplished and honourable members to differ more frequently than doctors differ. But I do say there is a strong temptation to them to act thus, and, if ever so honest, they may, unwittingly, be depriving another of his property. Not so with you, gentlemen.

Your business will be at all times, and in all places, to do good—to protect the sick and weak, to restore every man to his property—health. Your client is always the oppressed;

his adversaries are pain, disease, and death. To combat with these is your vocation, and to triumph over them can do no wrong to other men. You have the privilege of humbly imitating your Divine Master, who, while on earth, went about doing good, and healing all manner of sickness and all manner of disease among the people. The soldier's profession is esteemed a noble one, and so it is when exercised in a just cause—in defence of home and country—in defending the weak and protecting the innocent. But, alas! unjust wars are sometimes carried on, and the brave soldier must bear a part in scenes of violence and slaughter, at which his soul, in cooler moments, would shudder. He must fight and kill according to orders. Your task, my young friends, will be a better one. Not only in civil life, but even in the army and navy, your grateful duty will be to heal the wounds that others have inflicted; to bind up the broken limb and the broken heart; to soothe the pangs of suffering humanity. Friend and foe you treat with kindness, and save to the uttermost of your power. The laws of war allow this. At home or abroad, in civilized or in savage life, you are always to be the benefactor and the friend—the good Samaritan—often the confidential adviser, ministering to minds diseased as well as to their suffering bodies. This is your acknowledged mission, so that you are spared, and welcomed wherever you go, even amongst the bitterest enemies of your country or race.

Contrast a great physician with a great warrior—with an Alexander, or a Napoleon. The conqueror is called "great," estimating him, as we do the whirlwind, by the devastation he has wrought. The greatness of the physician is measured by the benefits he has conferred on his fellow-man—by the number of lives he has saved; and whether it is nobler to save life or to destroy?

It has been ascertained that one-sixth of all the persons who took small-pox in the natural way formerly, in London, died of the disease—a mortality which would now, in all probability, be occurring but for vaccination. Just fancy 200 deaths in London alone every week from small-pox! Two millions of people have died of small-pox in a single year in Russia, and of those who recovered thousands have been blinded or disfigured by this loathsome disease. Some persons here may recollect, as I do, the multitudes everywhere met with formerly, even in the middle and upper ranks, who lost their sight and had their faces seamed and pitted before vaccination was introduced. Now, on the contrary, how rarely do you hear of deaths from small-pox; how seldom do you see its disfiguring consequences? And to whom are we indebted for the introduction of this invaluable blessing? To a physician—Dr. Jenner. Who can calculate the amount of suffering that has been saved by chloroform judiciously administered! and it is to Physicians we are indebted for this—Dr. Waldie of Liverpool first suggested its use, and Dr. Simpson of Edinburgh (now Sir James Simpson) introduced it into practice. But time would fail me to tell of all the benefits, the miracles of healing, that have resulted from the discoveries of the Harveys, the Hunters, and a host of other medical men. Nor have the benefits conferred on mankind by medical men been confined to improvements or discoveries in connection with their profession. The justice of the great Samuel Johnson's remarks on this subject will be acknowledged by every one. He says:

"Wherever there has been any association of good men for laudable ends—wherever any institution has sprung up, having science or literature for its object, or any great scheme of benevolence been designed or perfected, medical men have been always found amongst their first—their most zealous and most useful supporters."

Even in Dublin, some of our finest institutions owe their origin to medical men. The first Lying-in Hospital in the British Empire was established in Dublin by Dr. Mosse, about a hundred years ago; and it is not only an ornament to the city for its architectural beauty, but it reflects credit on it as a School of Midwifery. It remains unrivalled in the British dominions for its extent, its usefulness to the poor, and for the character of its Medical

Officers; so that students come from all quarters to take advantage of the opportunities it affords.

Sir Patrick Dun's Hospital also owes its origin to a great physician, and so does Steevens' Hospital. These are establishments that do honour to our city, and speak volumes for the liberality of medical men.

I might also mention Jervis-street Hospital, Mercer's, and this, as in part, at least, owing their origin to medical men.

Other professions, too, as engineering, architecture, agriculture, the occupation of the banker and the merchant, though noble and honorable, seem to me to be less so than our profession. *They* have, like the others, to deal with property, *we* with life. They with the wardrobe, we with the person. They with what no doubt is useful and ornamental, but we with what is essential; and in none of them is the circle of the sciences required for their attainment so extensive, so varied, or so beautiful.

Now, why do I say so much in praise of our profession? Why draw comparisons between it and others? Not to lower them in your estimation—far from it—but I want to impress you with a sense of the true dignity and importance and usefulness of your own, that you may study it with deep earnestness, and with a nobler and better aim than that of mere moneymaking. I would have you believe that there is no profession more honorable, though some others are more honored and rewarded. Our profession is not crowned with the dignities and the princely fortunes which Government heaps upon men of other pursuits. No; the soldier is more necessary for advancing the conquests or sustaining the glory of a nation. Lawyers are more useful in governing a people; besides, they are generally the law makers, and can take care of themselves. All these, too, work in public; their efforts and success are seen by all, and men expect, very justly, that they shall be rewarded. But the medical man labours in comparative privacy; not in the camp, the court, or the senate house, but in the wards of an hospital, or in the silent chamber of sickness; *there* he is soothing some afflicted family, or trying all the resources of his art in the endeavour to restore to them again the dearest object of their affections, perhaps their greatest treasure, their only prop and stay.

You are not, however, to suppose that you will be unrewarded, even in pecuniary matters, or in fame. We could point to our Coopers and Brodies, our Cramptons and Colleses, and Carmichaels and Graves, and Marshes and Cusacks—not to speak of living men (which might be invidious) who realized fortunes and reputation sufficient to satisfy all your dreams of avarice or ambition. Again, you can enter the medical service of the army without purchase, taking rank, from the first, as a lieutenant, and with a captain's pay; while your brother, who had to pay a large sum for his commission as a combative officer, ranks only as an ensign, and lives, as best he may, on half your income. But I suppose you or your parents have well considered the necessary circumstances of your future income before you chose this profession. I do not want to hold out inducements to you to enter it; what I aim at is to stimulate you to study it, now that you have chosen it, with the higher motives and the better objects connected with it.

Perhaps I have said enough on this head, and will now proceed, in the *second* place, to give you some advice as to the mode of acquiring a knowledge of your profession. Well, in general terms, this must be done by reading, by lectures, by examinations, by manual practice, and by clinical observation. First, as to reading: The literature of our profession is enormous; you could not read in your whole life the hundredth part of what has been already written on medicine and the collateral sciences. While every year brings out such a number of essays and monographs, and compilations and systems, and cyclopedias and contributions, that it would be utterly impossible to keep pace with these varied productions. As a student, you will have time to read but few books. See

that these few be well selected by persons who understand the subject. Read them attentively, and master what you read. Better to read a little well, than a great deal superficially, and never sit poring and dozing over a book when your mind is fatigued; give it up for a time, and come at it again with fresh vigour. Have your own books, not borrowed ones, that you may mark with pencil important passages, and refresh your memory by looking over them again.

I hope you have all had a good preliminary education; that you have a competent knowledge of Greek and Latin; of history, geography, and chronology; of arithmetic, algebra, Euclid, and logic; that you write a good hand, and spell correctly. I should be glad, too, that you all understood French and German, especially French. Indeed, without a fair acquaintance with all the subjects I have mentioned, you will find it hard to get on in your studies, and will but imperfectly understand what you read or hear. Your prescriptions are in Latin; your technical terms are chiefly derived from the Greek; the names of diseases are, for the most part, Greek or Latin, and so are the names of the medicines. History, and geography, and chronology are brought in, constantly, when speaking of medicines or diseases, the effects of climate, the periods of epidemics, and the influence of manners and customs. Then, without arithmetic and algebra, geometry and logic, you cannot go along with the refined analyses, the accurate calculations, the close reasoning, the chemistry, and the natural philosophy which you have to study. Besides, all these are not only necessary as instruments, but they are most important in strengthening the mind and preparing it for close reasoning. Our profession has not only to observe facts, but to draw deductions from them—to reason upon facts—to distinguish well between coincidences and consequences, that we may not be led away by a *post hoc* as if it were a *propter hoc*. Moreover, the public expect that you shall have all this sort of knowledge. The doctor is expected to be familiar with every subject; and you will not only learn your profession imperfectly, but are apt in after life to sink in the estimation of your patients if you are not a well-informed man. I have heard of such an untoward event, and if you intend yourselves for the medical service of the army or navy you will be examined on many of these subjects.

It is to be regretted that a preliminary education, equal at least to that which I have here jotted down, is not insisted on by the different colleges. But I have no doubt it will, by-and-by. A near approach to it has been made by some of the licensing bodies, and even those which, a few years ago, gave their diplomas without knowing whether the candidate could read or write, now require a very respectable preliminary education.

But you may say, what use is it to tell us of this now? If we are not already thus educated, we cannot go back to these studies. Well, it is of use. Tell your brothers and young friends, who may be thinking of this profession, what they ought to do. Let them spend another year at school, or with tutors, and they will find that instead of losing time by this delay, they actually saved time by the ease and comfort and rapidity with which they got on afterwards, while their more ignorant fellow-students were awkwardly, and painfully, and slowly stumbling over the same ground. But even you yourselves may, in some degree, remedy your deficiencies. It is not too late. You might give an hour every day to the study of some of the subjects which I have mentioned, or even get a tutor to help you. And in your vacations, at all events, you could do a great deal in this way without at all trenching on the relaxation and amusements which you are entitled to after your winter's work. Many of you have sisters, and every lady knows French; let them teach you that language. It will serve to refresh your mind when wearied with severer studies during the session, or to afford you innocent and useful occupation when you have more leisure during the recess.

But enough of this. Your professional studies, what

are they? Anatomy, physiology, chemistry, botany, materia medica, surgery, and practice of medicine. The first five are the collateral, or rather the fundamental branches of knowledge, on which you build the last two—namely, surgery and medicine. The grand object you have in view is to learn how to treat disease in all its forms. Disease depends on some derangement of the mechanism of the body, or some abnormal condition of its functions. We must therefore make ourselves familiar with the structure and use of every part of the machine before we set about to repair it.

This wonderful machine consists of so many other machines, so varied in structure and use, in composition and action, yet all so harmoniously acting together, that we are filled with astonishment and admiration when we come to analyse and contemplate it. Wonderful and beautiful contrivances unfold themselves to view as we examine this machine of machines. We find there a framework of bone, firm and resisting, to support in one place, to protect in another, yet so movable as to allow of endless varieties of motion. How few consider that they carry about with them 250 such bones, some immovably bound together, others tipped with cartilage lubricated with synovia, to enable them to play freely one upon the other in all sorts of joints! How few think that they have 460 muscles to move and steady these bones! And then what is to become of these bones and muscles as they wear out? Such materials would not last a month in any human contrivance; yet they must last for three score years and ten. Well, there are myriads of vessels unceasingly carrying off the worn-out particles and supplying fresh. And the heart is by day and night pumping that fresh material through a thousand canals, at the rate of 100,000 strokes a day. And this material is prepared in the digestive organs from the food that we eat, then sent to the heart, then forwarded to the lungs to be purified, then carried back to the other side of the heart, to be pumped out into the system at large. Then there is a nervous system carrying sensations to the brain, and conveying the commands of the will from the brain—the minds' presence-chamber—controlling and directing everything, under the influence, itself, of that mysterious thing called Life. In fact, there are telescopes and microscopes, mills and chemical laboratories, galvanic batteries, a furnace, a forcing pump, waterworks and reservoirs, and filters, and so on—all wrapped up in a beautiful elastic, waterproof covering—so exquisitely organised as to resist injuries and protect the deeper parts, yet so sensitive as to give notice at once of anything that could injure itself or them. This machine of machines has moreover the wonderful power of repairing, to some extent, the wear and tear which it suffers, and the still more wonderful power of producing other machines like itself. Fancy a watch, as Paley remarks, possessing the property of producing, in the course of its movement, another watch like itself, and you will have some idea of the astonishing properties of a machine that can produce a piece of mechanism infinitely more complex than the most perfect chronometer. Anatomy makes us familiar with the structure of all this; shows us how fearfully and wonderfully we are made, and ought to lead, and does lead, a well regulated mind to admire and adore the Divine Artificer. Then physiology teaches the healthy function and use of every part, pathology the unhealthy, and by chemistry we become acquainted with the composition of the solids and fluids. Now can you conceive anything more absurd than to think that you could repair such a machine without a knowledge of its structure, and composition, and powers? If your watch were out of order would you employ a carpenter to repair it, or if a steam engine were spoiled would you send it to the shoemaker's? Yet this is the way the public act very often with regard to the most complicated and the most precious piece of mechanism that ever was formed. And you will be acting just as foolishly if you attempt to cure disease without the knowledge to which I have alluded. But this is not all; you must know the nature and properties of the instruments—

that is, the remedies with which you hope to cure. This is done by chemistry, and botany, and *materia medica*.

All this must be acquired by dissecting, by chemical experiments, by manipulation of medicines, by reading, by lectures, and by tutorial examinations, that you may be able to study, with effect, the practical part—that is, medicine and surgery, with its subdivisions—midwifery, dentistry, &c.

I have mentioned examinations, vulgarly called grinding, as one of the means of acquiring professional knowledge. This, if properly and judiciously used, is a very valuable means, but it is sadly abused in actual practice. If the grinder or private tutor, as he ought to be called, would direct his pupils as to the books to be read, or the subjects to be studied from day to day, and would examine him on them for, say, one hour a day, much good would be effected. But, unfortunately, he grinds them for three, four, five, or six hours a day—crams them with his “tips” and his “points”—leaves them no time for reading or for acquiring information by practice or observation; and it is said that some grinders have gone so far as to tell their pupils that they need not study at all, but may learn everything at the “grind.” The knowledge thus obtained is superficial, scarcely deserves the name of knowledge, merely exercises the memory, and though it may do much to “pass” a student and get him his diploma, it is soon afterwards lost and forgotten.

Now, you might have a thorough knowledge of the structure of the machine—that is, you might be a good anatomist, and have a masterly knowledge of the uses and functions of every part—that is, be good physiologists, and you might know all about chemistry and botany, and *materia medica*, yet be quite unable to bring your information to bear on that which is the end you have in view—namely, the proper treatment of disease. This you learn partly by reading, partly by systematic courses of lectures, which take you regularly over the long list of medical and surgical diseases, arranging and classifying them for you, pointing out errors in books, giving you the latest information respecting each malady, and telling you what the lecturer's experience is. This study and these lectures are very useful, but to give you a sound acquaintance with the practical part of your profession nothing can approach in importance clinical observation and instruction.

What is clinical instruction? Literally it means bedside instruction (*κλινη*, a bed). It is that which we derive from seeing and feeling and considering disease, as it actually exists before us; studying it, not in books, nor in lectures, nor in “the grind,” but in nature. Here in nature's own book you read the history, the causes, the varieties, and the symptoms of those numerous deviations from health which present themselves; the *diagnosis*, or distinction of one malady from another, never could be learned except at the bedside; the *prognosis*, or anticipation of results, would be vague, the application of remedies, or *therapeutics*, would be dangerous. In general, a writer or a lecturer can only tell you how to discover and treat a disease such as he saw it in one instance; or he paints an ideal portrait, with features taken from several cases bearing some resemblance to each other, and you may be able to trace a family likeness between that picture and the case before you. But no two cases are precisely alike, no more than two faces, and it very seldom happens that a disease is simple, and single, and uncomplicated; so that when you come to the bedside you are perplexed. The complications, the combinations, the modifications they undergo, from age, sex, temperament, hereditary or acquired peculiarities, and so on—these can never be told or described, they must be seen. And it is at the bedside you must learn the lesson which I wish you always to bear in mind—namely, that you are never to prescribe for a *disease*, but for the *patient* who is labouring under the disease—that is, you are to consider, not only what may be good for a given disease, but what will suit the patient in every particular, and with a due regard to all the organs of the body, as well as the one affected.

Quacks, by disregarding or not knowing this rule, often kill their victims.

Clinical medicine can be studied with effect only in an hospital. An hospital is a great laboratory in which all the processes of disease are continually going on. The powers of the complaint on one hand, the efficacy of the treatment on the other, are brought to the test. You will read in books of wonderful effects attributed to some remedies. Authors and discoverers, even when they intend to be honest, are often hurried into error by their enthusiasm and by their paternal regard for their own offspring. They are led away by an ardent imagination, or by some fascinating theory, to believe they have seen results which never followed, and to fancy they have conveyed benefits, of which no one else is conscious. Here these pretensions are put to the test. They are tried by some one who wishes indeed that they may be true, but who is not blinded by prejudice for or against. Sometimes these bold pretensions are found to be utterly baseless, sometimes to have a foundation in fact, or they may, happily, be confirmed to the uttermost.

When I talk of experiments going on before you in hospital, do not mistake me. Patients sometimes think they are admitted into hospital only to be experimented on, but such a notion is utterly false. No patients are admitted in order that they may be relieved, and if possible, cured. A conscientious medical man will try no experiment on his patients, in the bad sense of the word; but where two modes of treatment promise equal success, he will sometimes try one, sometimes the other. When any new remedy is recommended on competent authority, he will put it to the test on a suitable occasion. He would do the same with a private patient, or with a member of his own family, or with himself, if he laboured under the complaint for which it was recommended. And indeed it would be injustice to himself and to his patient not to give it a trial. It might be depriving the latter of a great boon. 'Tis true he oftener tries a new remedy in an hospital than in private practice, but so he ought; he oftener meets there first the case for which it is suitable; he can regulate times, and doses, and regimen more effectually; and he has trusty and intelligent house-surgeons or house pupils, and trained nurses, from whom he can learn particulars with accuracy.

I verily believe that patients in hospital are as faithfully dealt with as in private practice; that there is the same anxiety for their recovery; the same exertion of skill and attention; the same unwillingness to try dangerous or doubtful remedies; and more than the same amount of success, because there is stricter obedience to orders. I wish I could persuade you to watch these experiments with earnest attention. At first they may not interest you, but they very soon will if you follow them carefully. Attend at first as a duty, and you will soon feel pleasure in the task. As your knowledge increases so will your interest, and as you advance, and begin to reflect how the lives of your fellow-creatures will, ere long, be depending on your skill, all your energies will be roused, and every generous sentiment stimulated in the pursuit of your incalculably important profession.

Another popular error I wish to combat here—namely, that patients are teased, and sometimes injured, by being made the subjects of clinical instruction. Some few may be teased, but none are injured; and I have no hesitation in saying, that in most cases patients are essentially benefited by the custom of admitting pupils into hospitals.

I know it by my own experience, that I investigate cases with more care, and prescribe for them with more circumspection, and altogether do my duty to the sick more efficiently when I have intelligent pupils watching me, than when I am visiting the hospital alone. I cannot venture, under such observation, to hurry over a case. I must come to the real nature of the affection, and be able to assign a reason for everything I direct. Then as to patients being teased or annoyed, it is generally the reverse. Some do at first shrink from the searching gaze

of so many, but they soon learn that their complaints are now sought out in a way they never were before; and I have known them often and often flattered at attracting so much attention, and quite jealous if passed by without the scrutiny to which others were subjected. Of course we take care that pupils shall observe the strictest propriety in their behaviour, and avoid everything that could offend the delicacy or wound the feelings of the unhappy sufferers, or put them to any avoidable pain.

Well, then, how are you to avail yourselves most fully of the advantages here placed within your reach? You must be daily improving yourselves in those branches of knowledge which I before enumerated. Pay unremitting attention to your anatomy, both healthy and morbid anatomy, until, in the words of Dr. Hope, when looking at your patient, "you are able in imagination to turn him inside out," to see with your mind's eye every action, healthy or morbid, that is going on in the system, in every organ of the body, in the brain, the heart, the lungs, in the stomach, the liver, the kidneys—every bone, muscle, artery, and nerve in the body. Come to the hospital every day in time for the morning visit. Punctuality is of prime importance in learning, and the habit thus formed will be of use to you all your lives—giving you more time for the accomplishment of every work, and saving the time and the temper of others. And when you come, don't walk the hospital listlessly, yawning and anxious to be off, or with hands in your pockets, instead of holding your stethoscope, or educating your fingers for the *tactus eruditus*, by feeling everything that is abnormal, and helping to arrange every surgical apparatus, or noting down a case or the remarks made upon it, feeling a pulse, or familiarising your eye with the expression of countenance which is peculiar to each disease. Persevere in this course, not for a week or a month, but for the whole session, and you will be surprised at the end of it to find how much you have learned. I would advise you also to get a "Practice of Medicine," a "Practice of Surgery," and a "Pharmacopœia or Dispensatory; have them interleaved with writing paper, and at night read an account of the disease, or of the remedy which attracted your attention at the morning visit, and note down on the blank leaf your own remarks, or any information which you may have gathered from the observations of the visiting doctor.

This will prove an invaluable treasure during your studentship, and even in after life you will refer to this record in difficult cases, and it will recall to your memory with vividness many important facts and much practical knowledge which would otherwise have been lost to you for ever.

The practice of taking cases, noting down the history, the causes, the symptoms, and the treatment of a disease day after day while the patient is in hospital, you will find most instructive, fixing on your mind indelibly much important information, and training and strengthening your powers of observation.

And here I would impress on you the propriety, the duty, the absolute necessity of being kind, and gentle, and considerate, when dressing your patient, or questioning him about his complaint, or taking notes of his case. Recollect that he is really a brother in affliction; that his bodily feelings are just like yours, and his mind, perhaps, quite as sensitive. He may have been brought up as tenderly as yourself, and as little used to heartlessness. In fact, in all your dealings with your patients, whether rich or poor, in or out of hospital, never forget the golden rule laid down by our blessed Redeemer—"As ye would that men should do to you, do ye also to them likewise." You ought to give yourselves the habit of changing places with your patient, in imagination, and then acting as you would desire the student or the doctor to do. What a simple, and beautiful, and beneficent rule is this golden rule! How it would, if acted on, take from the misery and add to the happiness of mankind! Begin early, then, to practise it, and you will diffuse blessings around you without effort or trouble to yourselves, nay, with a delight

which the thoughtless, the selfish, or the unkind never knew. It is the more necessary to cultivate such feelings and principles early, because the practice of our profession, making us familiar with suffering, might, and perhaps sometimes does, harden the heart. But its general and usual tendency, under proper guidance, and in well-regulated minds, is the very reverse. It draws out the best and kindest sympathies of our nature, exercising and strengthening them, rubbing off, indeed, the morbid and maudlin sensibility which could not look on suffering, but would pass by it on the other side without moving a finger to relieve it. This passive sensibility is happily soon lost, while the manly, and genuine, and active, and practical sensibility, which flies to the rescue of the afflicted at any cost of health, wealth, or ease, or life itself, is more and more developed, and daily becomes more vigorous and effective.

I have now to tell you, in the *third* place, what helps we can give you in this hospital; and on this subject I must be very brief, as time presses. We, the Medical Officers, come here every morning, as regularly as we can, at the appointed hour; not all together, but at stated intervals, so that there may be a succession of us to conduct you round our different cases, without any waste of our time or yours. We question the patients before you. We dress them or prescribe for them, as the case may be. We dictate our prescriptions aloud, so that all may hear, and in Latin—both to familiarise you with the language, and to prevent the patient from knowing exactly the medicine he is using. This concealment is often quite necessary. A patient might be greatly alarmed if he knew he was taking arsenic, or prussic acid, or strychnine, and yet these may be the only remedies which, if judiciously used, are likely to cure him.

Then, our staff of Medical Officers may boldly challenge comparison with that of any other hospital. Four of them have been Presidents of the College of Surgeons; two of them Presidents of the College of Physicians; and of these, one had the singular honour of being President of both Colleges—a distinction never before conferred on any member of the profession. Most of them are; or have been, Professors in the College of Surgeons; Professors of Anatomy and Physiology, of Practice of Surgery, of Practice of Medicine, of Military Surgery, of Medical Jurisprudence, and of Midwifery. And one is Demonstrator of Anatomy; and one of our Consultants is the distinguished Professor of Chemistry in Trinity College; so that they have all the branches of the healing art, and the collateral sciences, familiar to them as household words. And most of them are long practised in clinical teaching; some as long as thirty-four years—during which time they have been accumulating experience, and acquiring a facility in communicating their knowledge. When I last delivered the Introductory Address we had in our corps one of the ablest men of which this city could boast, Dr. Robert Williams—a man not much known to the public, but held in the highest estimation by his professional brethren for his talents and acquirements, and beloved for kindness of disposition. After his removal we had the good fortune, as we then supposed, to elect a surgeon of equal value to the hospital—the clever, judicious, and amiable John Hatch Power; but death soon removed him also. These losses were deeply regretted; yet we are happy to say that, having secured the services of Mr. Croly, we have a successor every way worthy of such men. His untiring energy, his masterly knowledge of his profession, his admirable power of communicating information, and his boldness and success as an operator, have already won for him our entire confidence and given him a place amongst the most rising men of our city.

We have also made an important addition to our staff, which will prove of great value to you and to the patients. We have added three assistants to our hospital. We, seniors, cannot live always. We must train young men to succeed us. It is well to infuse young blood into the system of our institution. What we gain in wisdom and ex-

perience by time, may be counterbalanced by the loss of that active, forward, and progressive energy which the young possess; and it is wise to join the vigour of youth to the prudence of age. Accordingly, we have chosen Dr. Jacob, junior, as Assistant-Ophthalmic Surgeon; Dr. Benson, junior, Assistant-Physician, and Mr. Maclean as Dentist. We think the first of these will one day equal his father—it would be unreasonable to expect more. We hope the second will be a better man than *his* father—we cannot be satisfied with less. And we believe the third will not dishonour the name of Maclean, which stands so high in dental surgery. These young men will be able to give time and attention to matters which seniors could not attend to. They will bring under your notice the uses and the newest discoveries of the microscope, the laryngoscope, the ophthalmoscope, the endoscope, and so on. Keeping *you* up to the mark in all improvements, and giving the patients the full benefit of them.

But we and our assistants may be able and willing to teach, and yet not have the materials. Is our hospital large enough for the purpose? Yes; assuredly it is. It is many times larger than those which Richter and Scarpa had, and they were amongst the most distinguished teachers and practitioners of modern times.

Let me quote what Richter says on this subject—"There are only fifteen beds in the hospital at Goettingen, and I do not wish for more. I do not think that the experienced practitioner is formed by the number of patients. Experience is the result, not of seeing merely, but of reflecting; it is not eating, but digestion, that gives strength. A physician who tells us that he visits 150 patients daily has, in my opinion, so little pretensions to the title of an experienced man, that I would almost deny that he had any experience at all."

Now, without going quite as far as Richter, we think that, having five times his number of beds, we have quite enough to teach you your profession, and to do so in a more useful manner than if there were twice as many. You will find one case of disease closely watched from beginning to end more instructive than a dozen carelessly looked at.

How can a case be investigated, the changes which occurred since the former visit noticed, the tongue, pulse, skin, secretions, and excretions observed; the physical signs brought out, the prescriptions dictated, the diet directed, and the surgical manipulations of splints, bandages, dressings, &c., &c., according to the requirements of each case—how can these be accomplished on an average in less than, say three minutes to each case, or twenty cases in an hour? How, then, are you to get through all the cases of a large hospital in the time allotted for the morning visit, unless in a careless, superficial, and almost useless manner? And certainly the patient, who ought to be the prime object of our solicitude, cannot receive as much care and attention from his physician as in a smaller hospital.

But, although we might have contented ourselves, and satisfied you with the limited number of beds which we had in this hospital some years ago, yet the wants of this rapidly increasing neighbourhood called for further accommodation for the sick poor, and it was accordingly provided by the addition of several new wards a short time since; and we have now, in course of erection, another building, called the Drummond wing, in honour of the generous donor of £1000, which will still more effectually enable us to meet the pressing calls for admission, and to classify those that are admitted.

But it is time for me to conclude this lecture. I have to apologise for the length of it, and for the sermonizing tone it has sometimes assumed. But having your best interests at heart, I could not let the occasion pass. We are too apt to lose the opportunity of giving advice to pupils on their best and most enduring interests, and it is a great pity, for there is some tendency in the circumstances which surround a young man at the outset to lead him into many errors. It has been well said that an undevout astronomer is mad. I think an undevout

physician or surgeon is much worse. He is a dangerous madman. A medical man has a vast deal in his power for good or evil. He becomes the friend and confidential adviser in many families. He is made acquainted with their secrets, and if he be not a man of sound principles, of high honour, and of unblemished virtue, he might be the cause of incalculable mischief.

I may never again have the opportunity of delivering an opening address in this place. Before it comes to my turn again I shall probably have been called away to give an account of my stewardship; or, if spared to the close of another septennial period, it is likely that I shall prefer repose in the evening of my life, after a day of toil, to the excitement inseparable from the delivery of an opening address. Let me, then, my young friends, avail myself of this occasion to advise you to study diligently and perseveringly all the branches of your noble profession, and to cultivate those high principles to which I have been directing your attention. So will fame and fortune, *probably*, and so will peace of mind, an approving conscience, and the respect of good men, *certainly*, attend and cheer your walk through life, amid the arduous duties of an honourable but very anxious profession.

At the conclusion of the lecture, and frequently in the course of it, Dr. Benson was greeted with loud applause.

PUBLIC HEALTH AND SANITARY REFORM.

AN ADDRESS DELIVERED BEFORE THE DUBLIN STATISTICAL SOCIETY IN NOV., 1866.

By Sir R. J. KANE, M.D., F.R.S.

WHEN acceding to the request of the Council of the Statistical Society to open this session by delivering the annual address, I did not conceal from myself the difficulties which that task presented to me. I was quite aware that the subjects with which the Society has hitherto been principally occupied have only an indirect relation to the branches of science with which I have been more specially engaged, and that I could not presume either to comment upon the proceedings of the Society or to indicate the path which our members should pursue during the coming session with that authority which attached to the opinions of the eminent persons who in the late years have occupied the position which I now have the honour to fill. The gradual development and extension of the objects of this Society has, however, recently brought within its scope subjects of statistical and economic inquiry of not less scientific interest than any included within our earlier limits, and certainly of not less practical importance to the well-being of the people. Having commenced originally with the object of collecting, arranging, and discussing purely statistical facts, and avoiding the thorny questions of economic science, which was then scarcely considered separable from party politics, it has been only by degrees that the principles of political economy were admitted to the position of scientific truths, even so far as regarded the laws of population, of capital, and of commercial interchange. It has required still longer time and still further discussion before it was allowed that the distribution of wealth as well as its creation, that the condition of a population as well as the laws of its diminution and increase, could be considered upon purely scientific grounds, and could be extricated from the mire of political discussion. Even that advance has been, however, made; and in the expanded objects of statistical and economic science, the relations of capital to labour, of rich to poor, of the governing to the governed, can be impartially examined from the one as well as from the other point of view; and thus animating and directing the agencies of an enlightened philanthropy, may help to realize as a scientific law the noble sentiments of Bentham—that the true aim and object of society should be the greatest happiness of the greatest number of the people.

This remarkable development in the nature and objects of economic science has been fully represented in the proceedings of our Society for some time back, and our transactions will be found to contain many interesting papers suggesting or recording matters of social amelioration. A remarkable result of this new tendency of economic inquiry has been the establishment of the Social Science Congress, of which a very successful meeting took place in this city a few years back, and which in turn has given a still further expansion to the objects of this Society, which now embraces within its scope, not merely statistics and political economy, according to the older definition of those sciences, but includes also what is now understood by the name of the Social Sciences; in fact admitting as proper material for its labours almost every question affecting the material interests of society, the security of property, the health and education of the people—all of course treated upon purely scientific grounds, and independently of every personal or political consideration.

The scope of our Society has thus been extended far beyond its ancient bounds, and has necessitated a formal subdivision, which, although not strictly carried out, is yet as far as possible observed in arranging for the business of our meetings. Our objects are now declared to be the promotion of the study of statistics, jurisprudence, and social and economic science, and those objects are arranged in three departments, to wit:—

1st. Jurisprudence and the amendment of the law, including the punishment and reformation of criminals.

2nd. Social Science, including education, and political economy, including the principles of trade and commerce.

3rd. Public health and sanitary reform.

We have had at our last anniversary meeting the condition and prospects of the first of those three classes of subjects most ably and most eloquently discussed by Mr. Justice O'Hagan, who then occupied this chair. On the preceding anniversary, the second class of our objects which occupies itself with the more material interests of social life, was considered, in relation to that question of such paramount gravity in this country—the tenure of land—by Judge Longfield, the person above all others the best qualified by position and experience to express an authoritative opinion on that difficult subject. It has therefore appeared to me most suitable, as well as most simple, that your attention should be called on this occasion to the third branch of our objects—to wit, that of public health—a subject which, although but of recent introduction, is now recognised as of vast importance to the individual as well as to the state; and in regard to which, the nature of my own pursuits, having had some practical connection with many of the subjects which it includes, I may feel myself enabled to appreciate more accurately what the Society has accomplished within that field, and to indicate with more confidence the direction in which, as I believe, the labours of our members may be most usefully directed.

The importance of inquiries into the sanitary condition of the people, and the necessity for provisions being made on the part of the state for the preservation of the public health, has until lately been recognised only on occasion of the threatened invasion of some plague or other violent epidemic, and the preventive measures which the science or rather the ignorance of the times could devise consisted in an elaborately futile system of quarantine, and the form of destroying the contagious matter by fumigations, which had more resemblance to the magical ceremonies of an Eastern tale than to any real or scientific action. The true conditions upon which the maintenance of health depends, whether of individuals or of masses, were but very imperfectly known even to the best informed, and not at all to the common people; and it is a lamentable fact that the education still given even to the highest classes in our Public Schools and Colleges, leaves the pupils but too often ignorant of the most elementary principles of physiological and chemical

science; whilst the most valuable years of life are occupied with the minute details of Greek and Latin versification, a subject which to the great body of the learners can be but of very inferior importance. Within the last few years the necessity for a proper knowledge of sanitary laws, and the observance of sanitary conditions in the life of the people, has been recognised by the governing classes; and it is now generally understood that violent epidemics, such as that from which we are not as yet quite free, although creating great alarm and attracting universal attention by their rapidly destructive effects, yet, like the transitory though violent disturbances of our atmosphere, exercise but a subordinate influence on the real value of human life, or the true conditions of human happiness, as compared with the silent but continuous action of those preventible sources of disease which are everywhere and at all times in operation, and by which a much larger number of lives, that might have been saved to their families and to the state, are lost by ignorance and inertness. Under this stimulus, however, considerable progress has of late years been made in every department of sanitary science, and various legislative provisions have been devised to meet the more positive and prominent necessities of society. This increased attention to the subject has mainly sprung from those epidemics affecting both man and the lower animals, which have within the last few years assumed such national importance. The cause will, as I hope, prove temporary; the good effect shall, as we may trust, be permanent, and will be the origin of improved social arrangements better calculated to maintain the true conditions of health among the people.

The basis of all questions concerning the public health must be the rate of progress of the population, its increase in number, and the average value on duration of life. In regard to our population there is no doubt but that it continues to show a decided diminution, as the tide of emigration which still pours from our shores more than counterbalances the natural rate of increase from the excess of births over deaths belonging to a normal state of population. Our system of Registration of Births, Deaths, and Marriages is still of such recent introduction, and is still so imperfectly observed in many districts, notwithstanding the exertions of Mr. Donnelly, the Registrar-General, and his assistants, that we cannot attempt to deduce absolute conclusions from our own returns. It is not probable, however, that the true value of life in this country differs sensibly from the average of Great Britain, and by applying the co-efficients obtained from the more matured returns of the sister kingdom, we shall arrive at results in which I believe we may place confidence. Taking, therefore, the mean birth-rate at 1 in 31, the mean death-rate at 1 in 45, and the population of Ireland in September, 1865, as 5,626,471, we find that the births were 181,499, the deaths amounted to 125,033, giving an excess of births which should have increased our numbers by 56,466 in September, 1866; but that within the twelve months there had emigrated 107,053 persons, being an excess of 10,357 over the number which had emigrated during the preceding year, and converting our natural and proper increase into a most unnatural decrease of 50,587 by the loss of that number of the industrious and energetic members of the labouring classes, leaving behind them, a burthen upon the land, the idle, the imbecile, and the diseased. It is not within my province to refer otherwise to this stream, in which the life-blood of the nation is annually poured forth, or to consider how it could be arrested or diverted. A considerable diminution in the rate of loss is shown by the returns of the last quarter of this year, and the hope may be suggested that its greatest intensity has passed away. Many members of our Society are well qualified to discuss this question, and I have no doubt but that during the coming session it will receive proper attention.

I have mentioned that in calculating the above numbers, I employed the values for the birth and death-rates, as obtained from the British returns, those being, as I

believed, the more accurate. This merely arises from the more recent introduction of the system here, which renders it necessarily for some time incomplete. In every year greater exactness will be attained, and already we can trace in the returns of the present year greater completeness than in those of the year preceding. The value of life-birth—that is to say, the number of years which the life of any healthy individual of the community is likely to endure, is, in these countries, 41 years. The great problem of civilization should be to increase the value of life and to prolong that time during which the individual can be of service to himself, to his family, and to the state. But to be of service, mere existence is not enough: a population of fever-stricken, consumptive, or imbecile individuals could not support a state or constitute a nation; and it is therefore the necessary condition for human progress and civilization that proper provision should be made for maintaining the population in a state of health, so far as such can be done by human means. To this end several important legislative measures have been adopted of late years in the sister kingdom, and within the last few months, under the pressure of the alarm caused by the advent of the epidemic from which this country is not as yet quite free, we have obtained a consolidated and improved Sanitary Act for Ireland, organising under the direction of the public authorities an admirable system of control and supervision, through which it may be hoped that those agencies, whether of commission or of omission, by which disease might be generated or conveyed, may be, if not absolutely removed, at least materially narrowed in their range of influence and mitigated in their force. We are indebted to our able and energetic hon. secretary, Dr. Hancock, for an excellent report and digest of the enactments belonging to this subject.

The most indispensable requirements for the maintenance of health is personal cleanliness, full access of light, and proper supply of air. Without those conditions being fulfilled, a population will necessarily be short-lived, and even whilst living, will be so deficient in vital force and energy as to fall rapidly under the influence of any miasmatic or contagious virus which may happen to be generated or introduced. This subject has been well treated of by my friend Dr. Mapother, in his excellent lectures on hygiene delivered at the Royal College of Surgeons, in the reports which he has made officially as Officer of Health to the Municipal Council, and in papers which he has read before this Society. He has called special attention to the evils of over-crowding in the abodes of the poorer classes, to the entire violation of all sanitary laws, in which their wretched existence pines away. In every large town the tendency to overcrowding of the poorer classes of the people arising from their natural instinct of association, from the necessity for living near their work, from their ignorance of the dangers to which they are exposed, and the indifference or dislike to improvement which that ignorance engenders, has always been one of the most powerful agents in the spread of contagious diseases. In Dublin, owing unfortunately to the decay of a large portion of the city, by which mansions, once the residences of the rich and great, have become the tenements of the miserably poor, the evils of overcrowding do not take precisely the same form as in the manufacturing towns of Great Britain, where the constantly growing numbers of workmen accumulating within the same space has produced such bad results. Even in Dublin, however, and even in our provincial towns, Dr. Mapother has shown that tenements occupied by our working classes present some of the very worst features as to disease and filth that could occur, and it is fortunate that the lately increased powers which the Legislature has conferred upon the civic authorities will lead to the establishment of a standard of minimum accommodation which must be provided in all tenement lodgings under a direct unavoidable penalty. By such means a great deal of this evil may be abated.

In the prevention of disease, therefore, so far as hygiene

measures are concerned, you will observe that I place foremost those means which have for their object to elevate the standard of living, and to increase the vital force, to raise the life energy of the people. 1st. To enable, by cleanliness, the skin to perform those functions by which a proper equilibrium of the solid and liquid constituents of our system and the healthy constitution of our tissues is preserved. 2nd. By a proper supply of air to afford to the lungs the requisite means for aerating the blood, and supporting that combustion of the carbonaceous elements of the food by which the temperature necessary for the existence of animal life is maintained. And 3rd, to obtain full access of light, the true vivifier, the great source of energy in nature, without which neither chemical nor physiological action can be duly carried on. If those beneficent agencies are present, the influence of contagious miasma may be comparatively little dreaded. Those sources of disease of which we are only now beginning to have any real or scientific knowledge, are repelled by the energetic vitality of a healthy frame, and exercise their fatal powers in preference on weakened organizations.

The special means of cleanliness for the people must naturally be a copious supply of pure and well aerated water, not merely in such quantity as may suffice for domestic use, for the exigencies of personal cleanliness, and for public baths and wash-houses, but also what may be necessary for the complete removal of the debris and refuse materials which must accumulate wherever animals collect, and the decomposition of which proves often the most dangerous source of moral degradation and disease. Cleanliness is truly next to godliness; and there is no duty more imperative on those who have charge of the public administration of large cities than to provide abundant means for the removal of all collections of sewage materials from the inhabited places, and to afford, even to the poorest portion of the population, the means of personal and domestic purification. You are all aware of the great scale on which the proposed new water supply of Dublin is now being organised—the Clycpean reservoirs, the gigantic pipes, the successive stages of whose slow construction have been festively celebrated. Let us hope that before very long the expected water supply shall be actually placed at the disposal of the citizens, and that the promised advantages to the security of life and property against fire, to the health, the cleanliness, and the safety of the people may be realized.

The progress of investigation of late years has rendered probable that many, if not all, of the diseases which we describe under the term contagious, from their being in some way or other communicable from one person to another, are produced by organic germs capable of rapid reproduction, which, emanating from one diseased individual, may be carried through the air, or by means of clothing, or of another person himself not affected, and may generate the disease elsewhere, when they find a suitable situation. Such maladies constitute the class now known as zymotic or ferment diseases, as the contagious matter is believed to be analogous to the bodies termed ferments in their power of rapid reproduction and development, where they find suitable material to act upon. It would be out of place, even if time allowed, were I to enter here into any detailed account or discussion of those interesting questions of contagion. The phenomena are so varied, and apparently so contradictory, that until lately the question of the contagious or non-contagious nature of various diseases was keenly debated. Those questions have lost much of their importance now that we understand more accurately in what contagion really consists, and that the means of avoiding or contracting its influence are better known.

Some general observations on the nature of the matter of contagion and the processes by which it is spread, so far as the subject admits of popular explanation, may, however, not be considered irrelevant to the general sanitary question with which we are engaged.

(To be continued.)

NORTH CHARITABLE INFIRMARY AND CITY
OF CORK GENERAL HOSPITAL.

CLINICAL LECTURE.

By Mr. SHINKWIN,

JUNIOR SURGEON TO THE HOSPITAL, AND DEMONSTRATOR OF ANATOMY,
QUEEN'S COLLEGE, CORK.

GENTLEMEN,—The case to which I wish to direct your attention this morning is that of a patient who was admitted into No. 3 Ward on the 18th of August last, suffering from five scalp wounds, together with several severe bruises about his chest and abdomen, the result of a beating received four days before admission into hospital.

On examination we found the scalp wounds to vary in size from an inch to an inch and a half in length; the principal ones situated over left ear, over parietal suture, and over the juncture of the superior angle of occipital bone with parietals. He complained of the most excruciating pain in right side, extending from lower margin of eighth rib to about midway down the abdomen. This portion of the body was so painfully sensitive on being touched, that it was nearly impossible to make a proper examination as to whether there was, or was not, fracture of one of the ribs of that side, but my impression was that there was no fracture. All the wounds of the scalp were most carefully examined, but we could not discover any trace of fracture of skull, the pericranium only being removed in one.

I may remark here that the patient was a full, plethoric-looking country lad, aged 18, and on being asked any question it seemed painful to him to make a reply, but still there was nothing remarkable in the case to make us fear that the result would not be favourable.

On my visit the morning after his admission, Mr. Ryder, whose notes of the case I have before me, reported that the patient had been attacked during the night with rigors, vomiting, and most intense pain in the head, more especially in the frontal region, after which he became quite insensible, and was only roused out of the syncope (?) by the application of hot turpentine stupes to the stomach and chest, also to the calves of his legs. When sensibility returned, he was attacked with hiccough, which lasted fully ten minutes, and only seemed to subside as he gradually fell into a deep sleep, from which he woke in a profuse perspiration all over the body. On waking, he complained of being weary and tired, and did not remember what had happened. He now lies on his back, and can with difficulty be roused to answer the questions put to him, each time he makes the effort to speak sighing heavily. His pulse varies from 65 to 70; rather full.

As his bowels had not been moved since his admission, he was ordered a turpentine and assafœtida enema, with calomel and James's powders.

Now, gentlemen, permit me to ask you—What might give rise to the train of symptoms I have just related? Let us consider them in the order they occurred. First—The rigors, which, according to the report, were so severe as to shake the bed, might lead us to suppose that there may have been laceration of the brain substance, or that a portion of the internal table of the skull had been forced in on the brain, or that matter was forming in the brain, or that a vessel had been ruptured at the time of the injury, and had since then poured out its contents and caused compression. The vomiting is easily accounted for, as the sympathy between the head and stomach is so great that you have in almost all cases of injury of the head, be it either compression or concussion, vomiting occurring. The last symptom—insensibility—showed that there must have been some pressure on the brain, either from bone or fluid.

On the 21st—that is, three days after admission—he had another slight attack of rigors about half-past ten in the evening. I saw him at that hour, having been sent for by

our house-surgeon, Dr. O'Sullivan, and as his pulse was then only 70, feeble, and his skin inclined to be cold, I had hot tins applied to his feet, and gave him some warm wine and water. This appeared to serve him, and just as I was leaving the ward, he began to hiccough. I ordered him then two grains of calomel and the same of James's powder ever fourth hour, as also a chloric ether mixture.

During that night the frontal pain became so violent, and the patient so troublesome, that his head was shaved and cold lotions constantly applied. This plan of treatment relieved the pain very much up to eight o'clock next evening. Up to that hour he had taken his powders regularly. They acted slightly on the bowels; pulse 74, quiet and tranquil; respiration natural; pupils slightly dilated, but acted on by light; his friends say "he had always large eyes." At half-past eight o'clock he was again attacked with rigors, pain in the head, accompanied with violent muscular twitching of the hands, which at intervals became clenched. These attacks subsided after from twenty minutes to half an hour, but, unlike the primary ones, left no insensibility after them. He now for the first time since admission complained of pain in the spine, more referable to dorsal and lower end of cervical than any other region, and more at right than left side of body. He was ordered to be stuped with turpentine and mustard, which afforded him considerable ease.

On the 23rd, five days in hospital, the report reads:—"All the head symptoms much improved, but complains terribly of his right side and back, so much so that he lies altogether on left." I had Dr. Goolding, our assistant-physician, to see him, and after a careful stethoscopic examination we found that there was no internal lesion, and that the cause of the great pain was muscular soreness. He was ordered twelve leeches to the side, which were to be allowed to bleed well into a bran poultice; and as the head symptoms had subsided so much, to discontinue the powders. He is now taking beef-tea, and a glass and a half of wine daily.

Next day he was stated to have slept soundly for two or three hours consecutively, and seemed in all respects progressing most favourably; but after that calm came a surprise on us. At twelve o'clock same day (24th), he was awoke out of a sound sleep by regular tetanic spasms; his jaws locked quite tight; the muscles of the neck tense and rigid; his eyes fixed and staring, with greatly dilated pupils; his countenance gradually assuming all the appearance of a person attacked with tetanus. Hot turpentine stupes were immediately laid along his spine and over his abdomen, and the two o'clock report is—"The spasms greatly lessened in frequency; he can now open his mouth slightly, but on being asked to protrude the tongue, says it feels as if it were tied to the back of his neck."

At this sudden change in the character of the disease, we deemed it advisable to send for a magistrate to take his deposition, as to the manner in which he was beaten; during the examination he became quite faint and exhausted, and on the magistrates leaving, the spasms returned with their former violence. I was then sent for and ordered him a dessertspoonful of brandy every second hour; he swallowed slowly and with great difficulty, and could not bear to be raised up in the bed, fearful that the change of position may bring on the spasms. I gave directions for a large turpentine and assafœtida enema to be administered, as also to have a large blister applied to the occipital region, and a long narrow one down the spine. Under this plan of treatment the symptoms were greatly improved, and on turning to the report of the 26th (eighth day in hospital) we find all spasms gone, and now only complains of very slight pain in back; I may say he has taken no internal medicine since the spasms came on.

The 29th (eleven days in hospital), had a slight spasmodic attack this morning; was ordered a strong opiate liniment, which almost immediately checked them.

To follow out *seriatim* the various turns this case went through would be very tedious; suffice it to say, that he gra-

dually grew stronger and better, up to the 12th of September, when we had him walking about the ward—not, of course, very strong, but able to move with only the help of a stick; he has a slight halt in one of his legs. The improvement now became very marked, and he was able to walk down stairs to the garden on the 17th.

At this period of the case I was asked to give a certificate stating that he was out of danger, so as to enable six persons who were in confinement for assaulting him to be bailed; and as I thought that all danger to my patient's life had passed away, I gave the coveted certificate; when what was my surprise at being sent for on the evening of the 23rd, to come up to the hospital to see —. On arriving, to my great horror, I heard that he was worse than ever, that the certificate I had given was ignored, and that the six men were again to be placed in duress; indeed, I am sorry that I did not keep a note from a certain legal gentleman, in which he says, "The responsibility I took on myself was so great that it might be attended with very serious results if the man died;" but I had very peculiar ideas about the case for a few days previous, as it appeared rather extraordinary that he began to complain the day after I gave the certificate, and became more loud in his complaints as the day drew near when the six men were to be liberated from prison. The late Dr. Bullen saw him on the day of the evening I am speaking of, and ordered leeches and an aperient mixture. At twelve o'clock the same night I paid him a visit. He had been since my first visit removed into the small ward at the end of the corridor, and on my entering the room was lying on his back, breathing—pulse, tongue, and pupils natural; but at intervals varying from three to four minutes he started up in the bed, assuming the erect posture, during which time the pulse or breathing were not in the slightest accelerated. The moment I saw these movements my mind was quite at ease as to the probability of my being a resident in one of our Government country residences, as the spasms (?) were not such as to satisfy me of their being true ones. I immediately told my suspicions to Dr. O'Sullivan, and desired him to apply two large blisters over the patient's head. Dr. Bullen saw him with me next day, and we both perfectly agreed as to the nature of the case. Mr. Ryder's report of the 25th:—"Dr. Bullen told — if he was not better the following day his skull would be opened to get a look at his brain." This medicine appeared to have a peculiar specific effect, for, on going into the ward on the following morning, he inquired most anxiously whether his skull would be opened. And the answer given was, "get well as soon as you can, for if it is proved you are humbugging you will be transported." He was dismissed cured on the 7th of October. I have seen him since then; and he is perfectly well.

A great many practical hints may be learned from the case I have just read for you. When that man presented himself among the externs, there was something about his appearance that told me all was not right. On inquiring into the history of his case, I saw immediately that on the result of it other men's lives depended, and I took him into hospital. Had I not done so, I might have regretted it to the latest day of my life. When taken into hospital, for a day or so there was nothing especial to be noticed about him. The wounds in the scalp were not dangerous ones; they took on no unhealthy action. Yet, still in a day—nay, we may almost say in an hour, the man was dangerously ill, presenting all the appearances of compression of the brain, together with the symptoms of that most fearful of all diseases (one excepted, hydrophobia), which the surgeon has to contend with—tetanus; but yet he got well. Nature or art, or nature and art, which you will, helped, with the blessing of the Great Physician, to raise him from his bed, and make him again a healthy man. But, alas for human weakness! the puny arm of man had inflicted an injury, and in the restored health of the recovered was forgotten the feelings of the penitent sick. "I have suffered from their beating; I will make

them suffer more. They shall not be liberated so quickly as they imagine."

I am aware, gentlemen, it is uncharitable for me to argue thus, but facts are very strong proofs; and I think in the case under consideration that the facts bear me out in the conclusion I formed, that this man was feigning disease in order that the men who had been liberated on my certificate should be again arrested.

CASES OF SOFTENING OF THE BRAIN.

By JOHN W. OGLE, M.D.,

PHYSICIAN TO, AND LECTURER ON MEDICAL PATHOLOGY AT, ST. GEORGE'S HOSPITAL, ETC.

(Continued from page 300.)

SOFTENING OF THE BRAIN, ESPECIALLY OF THE WHITE CENTRAL PARTS; ARACHNITIS; DISEASE OF THE TEMPORAL AND OCCIPITAL BONES; PLUGGING-UP OF THE LATERAL SINUS BY FIBRINE.

Case 79.—Sarah B., aged 16, was admitted September 6th, 1849. She had been attacked two months previously with inflammation of the right ear, which soon produced deafness; and she stated that the membrane of the ear had been punctured twice without relief. On admission there was great pain in, and a thin discharge from the ear, and the membrana tympani was found to be destroyed. After a time small spicula of bone came away with the discharge, and by degrees the deafness on the right side becoming complete, the muscles on the right side of the face began to lose their power. A small polypus-like growth was found at the bottom of the external auditory meatus. This grew and eventually projected externally, and an abscess formed in the right temporal fossa, and over the mastoid process. Pus was evacuated by incision. The polypoid growth disappeared, but intense pain in the ear came on at night, which was relieved by incision through the temporal muscle. Another abscess formed and discharged near the outer canthus of the eye, from which bone came away; and another growth like the former grew from the meatus. Much carious bone was felt in the temporal fossa, and over the mastoid process. Great restlessness and weakness came on, requiring opium and stimulants. Low fever-like symptoms set in, and an attack supervened, termed by the nurse "a sort of fit." The patient became delirious, and a remarkable alteration in the voice was observed. The pupils of both eyes were very dilated, *but equally so*. No other special cerebral symptom came on before death, which occurred January 19th.

Post-mortem Examination.—The body was in good general condition. *Cranium.*—The dura-mater was very congested, and that portion covering both surfaces of the petrous part of the right temporal bone was very vascular, a small amount of recent fibrine existing between it and the bone; in the arachnoid covering was much thick purulent fluid, as also beneath on the sub-arachnoid tissues covering the upper part of the medulla oblongata, the right border of the pons varolii, and implicating the origin of the lingual, the pneumogastric, and the sixth and seventh cranial nerves of the right side, the two branches of the seventh being *softer* than natural. The middle lobe of the right cerebral hemisphere was more vascular, and softer than natural. The ventricles were distended, and contained much yellowish and opaque fluid, and the lining of the ventricles, especially on the right side, was very vascular. The corpora-striata, septum lucidum, and fornix were softened, and almost diffused, and the whole brain was rather softer than usual. Extensive caries of the mastoid, of the petrous, and in a slight degree of the squamous parts of the right temporal bone existed, and the styloid, vaginal, and auditory processes, together with the stylo-mastoid foramen were destroyed. Excepting the part forming the floor for the lateral sinus, the occipital bone was not affected.

The petrous part of the bone was so much destroyed that the cavity of the tympanum was laid open, and the bone forming the posterior boundary of the middle cranial fossa was destroyed, and much ulceration of the glenoid cavity, zygoma, malar bone, &c., existed. The lateral sinus was quite impervious to some extent, owing to its being occupied by firm fibrinous material. (36).*

GENERAL SOFTENING OF THE BRAIN; MANIA; EPILEPTIC ATTACKS.

Case 80.—Elizabeth P., aged 34, was admitted February 27, 1849, with symptoms of approaching mania, or insanity, and was unable to give much account of herself, but still appeared to understand things, and did as she was ordered. She had had several children, and miscarriages the last one two months previously, attended by much flooding. There were decided physical signs of congestion of the lungs, and of bronchitis, and she had had hæmoptysis. On the 28th, she had an epileptic attack which left her heavy and sleepy. The pupils were very contracted, the pulse was hard, and the urine passed involuntarily; on the following day mercury was given, and a blister applied to the neck, and the sore dressed with mercurial ointment. On the 5th of March she was quite maniacal, and had another fit. She sank and died the day after.

Post-mortem Examination.—Cranium.—The inner surface of the calvarium to the right of the longitudinal sinus contained a depression corresponding to an enlarged Pacchionian body, and two cerebral veins, before ending in the sinus, were of remarkable size. The brain was dripping with serum, and contained numerous bloody "puncta," and was somewhat softened throughout its substance. *Thorax and Abdomen.*—The pleuræ were much thickened. The kidneys were much diseased. Softening of all the central parts of the brain existed. Caries of the sphenoid and basilar parts of the occipital bone, and also of the upper cervical vertebræ existed, and also ulceration of the transverse ligament. (45.)

SOFTENING OF CENTRAL PARTS OF THE BRAIN; CARIES OF BASE OF CRANIUM; DELIRIUM AND UNCONSCIOUSNESS BEFORE DEATH.

Case 81.—William B., aged 30, was admitted April 25, 1849, having been ill about one month, and complaining of pain in the head, which was worse when lying down, and extended down both legs. He had an expression of much anxiety; his ideas were confused and he lay in a half conscious state. His speech was unnaturally slow and measured; the head was hot; the pulse was weak and feeble. In the evening he became delirious for two hours, but again recovered consciousness. He sank and died about twenty hours after admission.

Post-mortem Examination.—Cranium.—The cerebral membranes were natural. The brain generally was very soft, but especially at the central parts—viz., the septum-lucidum, the fornix, thalami optici, and corpora quadragemina. There was no increased vascularity. The pituitary body was large and rather soft, and the back part of the depression in the body of the sphenoid bone, in which this body lies, was partly destroyed by ulceration, and thus a hollow was formed, capable of holding a small nut, and filled with thick curdy pus. There was no communication between this cavity in the bone and the pharynx. The basilar part of the occipital bone was also very carious, as, likewise, the bodies of the upper cervical vertebræ. The inter-vertebral substance of the upper cervical vertebræ was ulcerated, and the "transverse" ligament connecting the atlas and axis almost entirely destroyed.† (89.)

EXTENSIVE SOFTENING OF THE FORNIX; SEMI-COMA AND DELIRIUM BEFORE DEATH.

Case 82.—John W., aged 14, was admitted June 28, 1849, having been ill with vomiting, followed, two or three days after, by much fever and constipation. There was also an unwillingness to put out the tongue or answer questions. His motions eventually were passed involuntarily. He was blistered and took calomel twice a-day. He recovered consciousness partly, but had a great inclination to sleep, and the pulse became irregular, slow, and, at times, intermitting. The pulse afterwards became quick and fuller, and he was delirious. He refused food, and sank and died July 11th. The bowels remained very costive.

Post-mortem Examination.—Thorax and Abdomen.—The lungs were congested. One lung contained a slight amount of scrofulous deposit, as did one kidney and the spleen, and slight ulceration of the bowel existed. *Cranium.*—The vessels of the cerebral membranes were congested, and the convolutions of the brain flattened. Many "puncta" were met with in portions of the brain, and the lateral ventricles and sub-arachnoid tissues were full of serum. The fornix was very softened, and quite broken down into a pulp when touched. (139.)

EXTENSIVE SOFTENING OF THE FORNIX AND SEPTUM-LUCIDUM; PHTHISIS, SO-CALLED; FAINTING ATTACKS BEFORE DEATH.

Case 83.—William C., aged 40, was admitted July 11, 1849, with fistula in ano and palmonary phthisis. About the middle of August he complained of headache and sickness; the tongue was furred and the skin hot. He was blistered, and the surface sloughed much. With variations, he went on till the 23rd, when he had two attacks described as "fainting fits," and died on the 24th.

Post-mortem Examination.—Thorax and Abdomen.—The right lung contained much scrofulous deposit, and traces of old peritonitis existed. *Cranium.*—The brain-substance was throughout much softer than usual, and the septum-lucidum so diffuent as to be quite perforated. The fornix was very softened; no exudation; corpuscles were met with in any of the vessels of the softened parts. (171.)

SOFTENING OF THE BRAIN GENERALLY, ESPECIALLY OF THE FORNIX AND SEPTUM-LUCIDUM; ERYSIPELAS AND SECONDARY DEPOSITS IN VARIOUS PARTS OF THE BODY.

Case 84.—Henry H., aged 17, was admitted August 1st, 1849. He had been of weakly health, and at the end of July became subject to headache and sickness. Erysipelatous inflammation of the face came on; also dyspnoea and pain at the left side, which were relieved by antimony and cupping the chest. Wine had to be given, but the hips suppurated, as did other parts of the body. Purulent deposits formed in several parts—on the knee, back, and shoulder—and on the 17th of August he was seized with convulsions, which were incessant. Diarrhoea came on, and great quickness of pulse, and he sank and died September 5th.

Post-mortem Examination.—Thorax and Abdomen.—Purulent deposits were found beneath the pleuræ and in the kidneys, and the cartilages of the elbow-joint were much destroyed. *Cranium.*—The brain-substance was generally softer than natural. The septum-lucidum was quite broken down, and the fornix quite pulpy. A slight amount of fluid existed in the ventricles. The membranes and the bones of the skull were natural. (181.)

SOFTENING (GENERAL) OF THE BRAIN; CONGESTION OF THE LUNGS; COMA BEFORE DEATH.

Case 85.—Samuel W., aged 32, a pot-boy, was admitted September 8th, 1849, in a state of delirium tremens of four days' standing. He had had a fit as they were taking him to the lunatic asylum. He was sweating much,

* For preparation of diseased bones of the ear, see Hosp. Path. Cat. Series xvi., No. 26.

† The preparation of diseased bone exists as No. 40, Series ii, in the Hos. Path. Cat., the case also described in Path. Soc. Trans., Vol. ii., 10.

and the tongue was moist and pasty. Porter with a drachm of laudanum was given him, and he lay in a state of stupor, constantly muttering, and with his eyes turned upwards and inwards. Sleep came on, with stertor and snoring respiration. In spite of brandy and opium, he became more restless and sank into coma, and died on the day of admission.

Post-mortem Examination—Thorax and Abdomen.—The lungs contained old cretaceous masses, and were congested. The heart was pale and flabby, with dilated walls. The kidneys were softened, with adherent capsules. *Cranium.*—The vessels and sinuses of the brain were congested, and the arachnoid membrane slightly opaque, with much fluid beneath. But little fluid existed in the ventricles. The brain was “wet,” and, throughout, in a softened condition. (184.)

SOFTENING OF THE CORPORA-STRIATA, THALAMI-OPTICI, AND UPPER SURFACE OF THE RIGHT CEREBRAL HEMISPHERE; HEMIPLEGIA ON THE LEFT SIDE; COMA BEFORE DEATH.

Case 86.—Mary H., aged 42, was admitted August 9th, 1849, with hemiplegia on the left side of the body. She had for some time been subject to fits of some kind. From this state she partially recovered, when she became a second time affected on the same side, after a severe attack of convulsions. Peculiar clonic spasms of the legs came on, and coma set in. She died three days after admission.

Post-mortem Examination—Thorax and Abdomen.—The lungs and kidneys were congested. *Cranium.*—The cranial bones were natural. The cerebral convolutions were flattened, and much serum existed in the lateral ventricles. The corpora-striata and thalami-optici were much softened, as were also the cerebral convolutions at the upper part of the right cerebral hemisphere. Corresponding to this softened part of the convolutions was a deposit of laminated yellowish-coloured material, apparently the remains of old blood-clot, attached to the inner surface of the dura-mater. This deposit was of the size of half-a-crown, and in its interior was a compressed cavity containing some scales of a silvery appearance, which could be peeled from the dura mater, to which it was pretty firmly attached.* (144.)

SOFTENING OF THE BRAIN IN GENERAL, ESPECIALLY OF THE FORNIX, AND SEPTUM-LUCIDUM; PHTHISIS; DELIRIUM.

Case 87.—John D., aged 46, a hard drinker, was admitted November 14th, 1850, in a low nervous state, and not very distinct in his answers, and with rather tremulous movements. He was feverish, and passed a delirious night, voiding his motions in bed. He expectorated purulent fluid, but his state was such that it was impossible to examine the chest. He sank and died four days after admission.

Post-mortem Examination—Thorax and Abdomen.—The lungs were congested, and contained much scrofulous deposit, as did the kidneys to a certain extent, and a part of the colon was in a state of scrofulous ulceration. *Cranium.*—Much fluid existed in the ventricles, and at the base of the brain. The brain was “wet,” and softer than natural, generally. The septum-lucidum and fornix were so soft as to be almost diffuent. (201.)

SOFTENING (GENERAL) OF THE BRAIN; PHTHISIS; PECULIAR CONDITION OF MIND; DELIRIUM BEFORE DEATH.

Case 88.—Richard P., aged 30, was admitted January 21st, 1852, in an apathetic and abstracted state of mind, leaving his sentences unfinished, and losing the thread of his ideas. He had had hæmoptysis and cough, and, for five weeks, diarrhœa and vomiting, and latterly pain in the

head, with partial deafness. The sight was indistinct, but there was no double vision. Consolidation of the lung was found. The tongue was red and moist. The pulse feeble and frequent. A blister was applied to the neck, and small doses of grey powder and Dover's powder were given. The head symptoms got worse. He became delirious. Sordes appeared in the mouth, strabismus came on, and he died January 28th.

Post-mortem Examination—Thorax and Abdomen.—Scrofulous deposits and vomicae were found in the lungs, and there was ulceration of the bowels and slight scrofulous deposit in the kidneys. *Cranium.*—The brain, generally, was “wet,” and also softened altogether. Much fluid existed under the arachnoid, and slight turbid fluid in the ventricles. (25.)

PATCH OF SOFTENING IN THE LEFT CEREBRAL HEMISPHERE; SCROFULOUS DEPOSIT IN THE LUNGS; DISEASED KIDNEYS; DELIRIUM AND COMA BEFORE DEATH.

Case 89.—Thomas T., aged 54, an intemperate man, was admitted June 6th, 1852, having in a drunken fray injured his elbow and divided several of the veins. On the day afterwards delirium set in, and opium and bark were freely given. His manner was very strange and tremulous. After being violent for a length of time he fell into a comatose state, and died on the 19th.

Post-mortem Examination.—The injury about the elbow was in a sloughy state, and some of the veins, where divided, had open mouths, and contained puriform fluid. *Blood.*—In the heart and all the large vessels the blood was very fluid, and contained pus-globules and granular matter. *Cranium.*—Much fluid escaped on removing the brain, and the vessels of the pia-mater, which was puffy and thickened, were very injected. The surface of the cerebral convolutions generally was softened, and on the upper part of the left cerebral hemisphere was a small circumscribed patch, where the brain-matter was diffuent, and had almost the appearance as if it had been bruised. The whole brain was “wet” and pale. *Thorax and Abdomen.*—Scrofulous deposit existed in the lungs, and the kidneys were very granular. (136.)

SOFTENING OF THE CENTRAL WHITE PARTS OF THE BRAIN; PHTHISIS; PTOSIS, SYMPTOMS LIKE THOSE OF FEVER.

Case 90.—Alfred S., aged 15, was admitted August 19, 1852, in a state of partial stupor, and when roused relapsing into somnolence. There was much fever and the pupils were dilated; there was also drooping of the left upper eyelid. Purgative injections, and also calomel, were given, and cold was applied to the head, and, under the impression of the case being one of fever, large doses of quinine were given every six hours, which had the effect of reducing the pulse. The nights became quieter, and he became more intelligent. He complained much of pain in the head. Both pupils continued dilated, the left one being especially sluggish. No petechial spots were ever found on the skin. Unmanageable delirium came on and passed into stupor. The urine was alkaline and loaded with phosphates. The evacuations became passed involuntarily, and coma preceded death, which happened August 27th.

Post-mortem Examination—Thorax and Abdomen.—The lungs contained much scrofulous deposit and vomicae, as did the spleen. The colour was ulcerated. *Cranium.*—The meningeal vessels were very congested, and the ventricles were distended with fluid. The central white parts of the brain were much softened. (169.)

SOFTENING OF THE CENTRAL WHITE PARTS OF THE BRAIN; PARALYSIS, FIRST OF THE LEGS, AND THEN OF ALL THE LIMBS; CONVULSIVE ATTACKS.

Case 91.—Richard H., aged 48, was admitted August 11, 1852. He had had stricture for some years, and for a short time had been under treatment for stiffness, weakness, and numbness in both legs, from which he had

* The dura mater is described in the “Hosp. Path. Cat.,” Series viii., No. 189.

suffered for six weeks. For some time he had been unable to retain his evacuations. On the morning of admission he had an attack, in which he lost his senses and was convulsed, and on recovery he had lost all power of motion of the limbs on the left side, the sensibility of the skin being unaffected. He was cupped between the shoulders and purged. The speech was indistinct, and the mouth drawn slightly to one side. A blister was applied to the neck, and small doses of grey powder were given. On the 6th September, giddiness, pain in the head, and great inclination for sleep, with double vision, came on. He had lost all power in the hands and feet, and all evacuations were passed involuntarily. Several convulsive attacks came on, and the urine became transiently albuminous. Excepting some slight use of the right arm, he had lost power over all the limbs. He became perfectly powerless, sloughs formed on the back, and he sank and died November 3rd.

Post-mortem examination.—Cranium.—The bones of the skull were unusually thin. The lateral ventricles were twice the usual size, and full of limpid fluid, and the fornix and all the central parts of the brain were very much softened. *Thorax and Abdomen.*—The lungs were much congested at their lower parts. The kidneys were also diseased. (219.)

SOFTENING OF THE SURFACE AND CENTRAL WHITE PARTS OF THE BRAIN; DISTENSION OF THE VENTRICLES; CICATRIX IN THE CEREBELLUM; STRUMOUS DISEASE OF THE LUNGS AND KIDNEYS; GENERAL PARALYSIS OF THE INSANE.

Case 92.—James T., a tailor, aged 36, became a patient of mine at the St. George's and St. James' Dispensary in the early part of November, 1852. He had rather a starved look, and slight lachrymation of the right eye, also a noticeable slowness of speech with a slight lisping; but he was in tolerable general condition. There was no alteration of the muscles of the face, and the sight and hearing were good, but there was ptosis of the right upper eyelid, and the pupils were rather dilated. His manner was good and his mental faculties apparently tolerable, but his temper and spirits were very variable. There was no loss of sensibility in the skin, nor of motive power in any of the limbs, and he walked well, complaining of no pain, but of occasional "creepings and twitchings" of the left arm and leg. There was slight occasional cough, but nothing wrong was to be found in the heart and lungs. He related that his illness had existed several months, commencing with giddiness, with pain in the head, and gradual loss of power on the whole of the left side, but that, after a time, the power of the limbs returned. He had never been intemperate, but had gambled much, and had had much trouble. I put him on small doses of the bichloride of mercury and bark, and blistered the nape of the neck, and continued the treatment for a month. At the end of that time his wife said his disposition was more even, his aspect more cheerful, and his speech improved. The gums were slightly touched by the mercurials. About the middle of December he began to complain of occasional staggering, and temporary numbness in all the limbs, causing him to stretch them, by which the feeling would pass off. He then had two seizures, in one of which numbness and tightness affected all the body, in the other attack only the left side. He often started in sleep, and the left leg would start up. His mouth becoming sore, the mercury was omitted. At the beginning of February he had more of the attacks of general numbness, crying afterwards; and at the beginning of March he had an attack in which he lost the power of the left arm and leg, but the speech was not affected. He thought he became near-sighted. Quinine and, subsequently, strychnia, were given him, and mercury, from time to time for short periods. After going on without any further change, but having occasional attacks, and losing strength, he went into the workhouse, and eventually was transferred in a decided state of

"general paralysis of the insane" to Colney Hatch Asylum, May 23, 1854. The disease of the brain, and its paralytic concomitant, "general paralysis," were progressive (as Dr. Tyerman was so good as to inform me) until his death, November 2nd.

Post-mortem Examination.—There was great emaciation, with imperfect cadaveric rigidity of the limbs. *Cranium.*—there was great vascularity of the surface of the brain; the veins large and tortuous. The arachnoid membrane was opaque generally, and much fluid existed beneath it. The cerebral membranes were greatly thickened. The grey substance of the brain was universally soft and high coloured. A small patch of ecchymosis existed at the vertex on the right side of the brain (in the sub-serous cellular tissue). The ventricles were greatly distended (all the cornua well developed), and filled with clear fluid. The septum-lucidum and fornix were generally soft, almost disorganized. The lining membrane of the ventricles was opaque and thickened. The velum and choroid-plexuses were congested. Much serum existed at the base of the skull; the effused fluid in this situation, together with what was in the ventricles and the sub-serous cellular tissue of the pia-mater, amounting to eight or ten ounces. The weight of the brain, including the cerebellum, was two pounds ten ounces, avoirdupois. The commissura mollis was absent, probably owing to laceration by separation of the walls of the third ventricle, owing to the accumulation and subsequent absorption of fluid; and in the posterior and inferior lobe of the cerebellum there was a gelatinous cicatrix, intimately connected with the membranes and substance of the organ. *Thorax and Abdomen.*—Old pleuritic adhesions existed on both sides, more marked on the left. The lungs were expanded and crepitant generally. The right superior lobe was rather solid, and in its apex was a considerable (old) cicatrix, and deep in its substance a mass of cretaceous tubercle. The heart was pretty well contracted; firm fibrinous coagula existed within the right cavities and large vessels. In the pericardium there existed about one ounce of yellow serous fluid. The liver was large and solid, purple and heavy; its capsule thickened; its inferior border thickened and rounded; its substance very firm and heavy, and loaded with pitchy blood. The kidneys were rather large and highly congested, the pelvis and ureters highly inflamed, and containing purulent mucus; and in the cortex of the right kidney there existed a circumscribed tubercle, the size of a small bean. The bladder was contracted, its mucous surface was highly inflamed, and in its cavity was an ounce or two of urine, containing pus with mucus.

SOFTENING OF THE CENTRAL WHITE PARTS OF THE BRAIN; INCIPIENT KIDNEY DISEASE; DELIRIUM TREMENS; CONVULSIONS.

Case 93.—John W., aged 34, was admitted March 28, 1853, in a state of delirium tremens, having tried to commit suicide by cutting his throat superficially. He had been two nights without sleep, and on the night of the 29th he had three fits, in which he became blue in the face, foamed at the mouth, and bit the tongue. Æther, gin, and laudanum were given. No sleep was procured, but he became violently delirious. It was resolved to give him chloroform to inhale, but as a fit was threatening, it was relinquished. Opium suppositories were had recourse to, and again was the inhalation of chloroform attempted, but as another fit seemed to impend, the attempt was a second time discontinued, and he died exhausted, April 1st.

Post-mortem Examination.—Abdomen.—The kidneys presented marks of early disease. *Cranium.*—The cerebral membranes were congested, and much fluid existed under the arachnoid and in the ventricles. The central white parts of the brain were softened. (68).

London Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 5, 1866.

THE MEDICAL STUDENTS IN 1866.

IN the general dearth of topics with which the political newspapers are periodically affected at the present season, the *Times* has fallen foul of the Medical Students, and has devoted half a column of pretty large type to a letter from one who signs himself a "Medical Tutor," and who complains most bitterly of what he terms the "increasing demoralisation" of this class of youths. The text of his remarks is drawn from the rather riotous conduct of some persons, said to be Medical Students, at the lecture delivered lately at St. James's Hall, by Dr. MARY WALKER, and from a silly story which went the round of the papers as to a Medical Student at St. Mary's Hospital having poked a dead body with a stick during a Coroner's Inquest. The writer having thus illustrated the observations he makes, proceeds to explain the causes which have given rise to the demoralisation in question, and he believes them to exist in the want of control over the body of Medical Students on the part of the teachers and lecturers, and in the eager competition of the schools for pupils. In many of the Medical Schools, he observes, not the least discipline is ever attempted, far less maintained, while the most idle and dissipated students may obtain certificates of attendance on lectures at which they were never present, and gain credit for diligence which they have never evinced.

This letter, as may readily be supposed, immediately called forth some indignant replies from writers who denied altogether the sweeping accusations thus made, and who claimed for the Medical Students of the present day as high a degree of respectability in general demeanour as is shown by any other class of the community; and the conduct of the general body of students is contrasted with that of the alumni of Oxford and Cambridge, who, as is well known, are occasionally guilty of outbursts of violence. One of the writers who thus vindicates the students from the charges made by the "Medical Tutor," alleges that the latter has had no experience, or a very exceptional one, with the actual work of hospital teaching; and he then appeals to the lecturers whether it is not their own faults if they fail to obtain respectful attention from the classes they teach. But while we admit that the "Medical Tutor" is too severe in his remarks, and that he attributes to the whole body the perpetration of offences which are committed only by a few, yet we cannot but admit that there is considerable force in some of his observations as to the present condition of medical students in our large cities. It is quite true that there is no control exercised over this large class of young men, except perhaps

when they are within the walls of the College or Hospital; and what is much to be deplored, there is none of that sympathy and kindness, except in particular instances, shown to the diligent and well conducted students, which may, in some measure, compensate them for the absence of home-comforts and the advantage of parental advice. Since the practical abolition of the apprenticeship system, the young men of our Hospitals and Medical Schools are left to do pretty much as they please, and it is a matter for congratulation that their general conduct is as good as it is. Many well-wishers to the Profession, however, are desirous that something like a collegiate system should be adopted for the benefit of our Medical Students, whose moral and intellectual progress might be watched with more care than is at present bestowed, and whose occasional irregularities, even if they could not be prevented, might at least be reported to their parents or friends.

CHOLERA.

OUR weekly chronicle of cholera happily continues to grow less interesting as its figures progressively diminish, and we are looking forward to our next volume with the pleasing hope of being able to devote its columns to other subjects. In the forty-seventh week of the year there were 8 deaths from cholera and 26 from diarrhoea, in the metropolitan districts. This is the first time since the commencement of the epidemic that the deaths from cholera, in any one week, have been less than the deaths from the milder form of disease. The deaths from cholera during the last seven weeks have decreased as follows: 207, 144, 112, 73, 67, 32, and 8.

The total deaths in London during the week were 1435, which is less by 173 than the average number, corrected for increase of population. It must be allowed that these figures present a very favourable account of the health of the metropolis. This state is probably partly due to the energetic measures that have been adopted to meet the cholera, and which cannot be without their effect on the other zymotic diseases. It also constitutes the strongest possible argument in favour of the continuance of every kind of sanitary precaution. There is no need to set up an alarmist cry, yet there is abundant reason to warn the authorities that we are not yet rid of the pestilence, and that it is quite possible we may have to encounter a renewed outbreak in the coming spring or early summer. We have now a respite. Let it be employed in stamping out the seeds of the disease, and abolishing these preventible nuisances from which zymotic disorders draw their power of destruction. It may be taken as an encouraging circumstance that on several days there have been no deaths from cholera in all London. On Sunday, 25th, there was only one; on Monday and Tuesday none.

LIVERPOOL.

The Medical Officer of Health has certified that cholera has now dissipated from the town, and clean bills of health are now granted to vessels leaving the port.

EDINBURGH.

The weekly return shows a fall of 50 per cent. in the deaths. Nine cases were reported, of which 4 had proved

fatal. In Leith, 5 more cases. In Leven, 4. A fearful outbreak occurred at Methill Hill, a colliery village of 350 inhabitants, of which it is stated one-seventh perished in four or five days, and the disease was not abating. In this village, and three others near, it is stated more than 300 deaths from cholera had taken place. The people have fled in large numbers, and the disease is reported to be propagated by the fugitives throughout the country.

HEALTH OF THE CITY OF LONDON.

THE Quarterly Report of the Medical Officer of the City has just been presented to the Commissioners of Sewers, and embracing as it does a period of unusual importance, demands some notice on our part.

There were 655 deaths registered in the City during the summer quarter, being at the rate of 22.9 per 1000. The mortality for the last ten years in the same quarter has averaged 20.6; yet although the mortality has been larger than usual, it has not been equal to that of the rest of London, nor to that of all England. Of the 655 deaths, 228 were those of children under 5 years of age; there were 60 deaths between the ages of 5 and 20; 135 between 20 and 50; 146 between 50 and 70; and 86 at the age of 70 or upwards. Comparing these figures with the averages of the last ten years, it will be seen that the mortality last quarter was less than usual in young children, and considerably greater in persons of advanced age. This may be due to larger numbers residing outside the City boundaries, and the consequent decrease in the number of births that take place in the City. There were 117 deaths from tubercular diseases, 42 from inflammatory affections of the lungs, and 248 from zymotic diseases. The average numbers for the same quarters of the last ten years are—146, 55, and 172. There has, therefore, been less than usual disease of the two first classes, with a great increase in the last. This excess has been entirely due to "alvine disorders," and these have been most fatal in adults, having caused altogether 152 deaths, of which only 49 were those of children under 5 years of age, thus leaving 103 deaths of persons above 5, the average mortality of the last ten summers in persons of this age being only 10. Pursuing this subject, we learn from Dr. Letheby's report that there were 53 deaths from cholera, 2 from choleraic diarrhœa, and 11 from diarrhœa, among the adult population of the city, and 9 from cholera, 5 from choleraic diarrhœa, and 29 from diarrhœa, among the infantile population (under 5 years of age).

In the City workhouses which are situated outside the City there were thirty-two deaths from cholera and six from diarrhœa. These figures prepare the reader for the statement that the City has only been slightly visited. It appears in fact that the total mortality from cholera and diarrhœa in the City Unions, including the inmates of the workhouses in the suburbs, has been 13 per 10,000, while in all London it has been 22. The following figures show the weekly deaths from these diseases, commencing with the week ending July 14:—

1	.	0	.	7	.	18	.	15	.	8	.	7
2	.	3	.	7	.	6	.		.		.	

Of these deaths, nearly three-fourths occurred in the eastern portion of the city; but Dr. Letheby states that, "*there is no evidence of its having been caused by the use of the water of either of the water companies which supply the City. On the contrary, its propagation and occurrence have been, as usual, among the poor and ill-conditioned.*"

This statement is of such importance, and everything coming from so able an authority as Dr. Letheby is so deserving of full consideration, that we have taken the liberty

to italicise it. The position of Dr. Letheby as Professor of Chemistry at the London Hospital has afforded him the opportunity to investigate this point in the much more severe outbreak at the east of London, and as he proposes to "deal with the subject more fully when the now fast-waning disease has left us," we shall look anxiously for his matured opinions in his next report. We have heard so much lately of water as the origin of the epidemic, that a disposition to doubt the accuracy of the conclusions so freely circulated will infuse considerable freshness into the subject.

The sanitary labours of the quarter, to which, we doubt not, the favourable returns are in great part due, are all detailed in the report before us, and although we cannot afford space to reprint them in full, we feel bound to state that they do great credit to the Medical Officer of Health for the City, and the subordinates who faithfully carried out his instructions.

Notes on Current Topics.

DEATH OF M. TROUSSEAU.

THE sudden death is announced of Professor Trousseau, the great physician of Paris. Dr. Trousseau was one of the most eminent and highly distinguished physicians whom the school of Paris has produced. He combined the highest qualities of the teacher with the most remarkable skill as a practical physician. His clinical insight was exquisite; the profound, literal, and minute study which he made of every case was the first element of his success. But to this he added rare sagacity and discrimination, a searching insight into hidden causes, and a skill in unravelling the most intricate web of probabilities, which rarely failed him. It was impossible to hear Trousseau give an account of even the most usual case without feeling that he had invested it with a peculiar interest, that he saw more in it than any ordinary man could see, and had called attention to some subtle analogy or some suggestive detail which would have eluded any but his keen glance. Not the least of his qualities was an admirable precision of language, and a fluency which, under the influence of feeling, often warmed into eloquence. He was erudite, as most eminent French physicians are; but he was more catholic, more sober, and less enamoured of novelties, than many of his distinguished contemporaries in that school. We pay him a compliment which he appreciated, which in his lifetime he loved to hear, in calling him the French Graves. He highly esteemed the clinical writings of that physician, and edited them in French. His own clinical lectures, which are now in course of publication in English, forcibly recall those of his great Irish predecessor. He had but lately resigned the Chair of Clinical Medicine in the Paris Faculty, which he had been induced to keep of late years, sorely against his will, by the earnest prayers of the students, who idolised their great teacher. In this country, Trousseau has long been accepted as the best typical physician of the French school. His sudden decease will not be heard here without emotion by many private friends, and by more professional admirers.

PROFESSOR WEDL ON TRICHINIASIS.

A REPORT of a Committee on Trichiniasis has been presented to the Medical Society of Vienna by Professor Wedl. The Committee dealt mainly with the presence of the disease in different animals, &c. Rats taken in Vienna and the suburbs, as well as in many of the provinces of the empire, were especially examined with this object. Very few trichinæ were found in Vienna rats. On the other hand, suburban rats, and the Moravian and Galician rats, were

found well studded with the parasites. In Moravia, for example, where there are an extensive manufacturing of sausages and large pig-markets, trichinæ abounded. Trichinæ were also found in the marmot, hedgehog, shrew-mouse, polecat, and fox. But in pigs, for the most part, the examinations were negative. Hitherto, there have only been in Austria a few scattered cases of trichinosis observed in man. The pigs experimented on exhibited no distinct pathological symptoms characteristic of trichinosis. Cough and irritation of the skin, loss of appetite and wasting, were noted, but after a time disappeared. The same symptoms were noted in a calf. Experiments with tainted food made on rats, mice, foxes, &c., all gave positive results. But in no case was paresis or paralysis observed. Trichinæ subjected to gastric fluid were destroyed; but the capsulated trichinæ resisted destruction. Muscular trichinæ exhibited great tenacity of life in decomposed muscle; they were still capable of infecting after being kept eighty days in putrid flesh.

LOGIC AND SUPERSTITION.

In a recent able review of the biography of Dr. Whately, the late Archbishop of Dublin, the writer refers to the singular facility with which that great logician gave himself up to all the wild follies of mere sciolists and pretenders in science. Homœopathy, animal magnetism, spirit-rapping, and most nonsense of the kind, found ready acceptance from him. This writer has a theory by which he explains the paradox. It is, he says, "as if, in his case, as in that of others, the intense use of reason produced a reaction towards superstition in some matters." The same thing has been enunciated more generally by Dugald Stewart, who says "that mathematicians are the most credulous of men." An illustrious living mathematician in the metropolis is very well known at the present moment as one of the warmest believers in the mysteries of spirit-rapping and spirit communications.

Hospital Reports.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

Dr. LYONS' CLINIQUE.

IDIOPATHIC TETANUS—TREATMENT BY TOBACCO AND NICOTINE.

(Reported by Mr. CRAWFORD, Clinical Clerk.)

PATRICK McGRATH, æt. 10, was admitted into the Hardwicke Hospital, October 28th, 1866. He had all the symptoms of general tetanus, well developed; partial trismus was constantly present, and opisthotonos recurred at frequent intervals both by day and night; the muscles of the back of the neck were rigid, and when a spasm came on his head was thrown forcibly back, the muscles of mastication were also implicated, so much so that he could not open his mouth more than a quarter of an inch. He was found to present pneumonia of the left lung; the face was flushed; perspiration broke out whenever a spasm attacked him. None of the muscles of the lower extremities was affected; the spasms recurred every few minutes, throwing him backwards, arching his spine; at the same time he experienced great difficulty in breathing; the doors and windows had to be opened; while he was in this state the muscles of the abdomen would be like a board; by pressing on them he found great relief; sometimes it took all the

weight and pressure his nurse could exert to control the tension and suffering experienced in the abdomen.

No wound, scratch, or external injury of any kind could be detected.

The previous history of this patient cannot be accurately found out; he had been ill since Thursday, 25th, when he first felt pain in the muscles of the abdomen; from that date he seems to have been getting worse every day, and on Sunday (28th) morning, after a severe night, his mother brought him to hospital.

That evening, by direction of Dr. Lyons, an enema was given of tobacco $\mathfrak{z}i.$ to $\mathfrak{z}xx.$ of water, $\mathfrak{z}v.$ of which were injected; the effects were very marked, for after a few minutes he became quite unconscious, and all the muscles were relaxed; this state did not last longer than a quarter of an hour, when the tetanic symptoms recurred, but with less urgency than before.

October 29th. Had a great number of attacks during the night; slept none; suffered from flatulence, which was greatly relieved by enemata of turpentine, which brought away a quantity of hardened fæces.

An enema of tobacco was given in the evening, not so large as the former one; the effects it produced were not so marked.

Enemata of turpentine were given to clear out the bowels, which was not fully accomplished for a number of days.

30th. The patient is slightly improved, but he is still affected with repeated attacks of the spasms, of which as many as forty-five were counted during the day and night; the breathing is still difficult; expectoration of a frothy mucous character; cannot cough it up; but instead makes strong expiratory efforts; drinks milk and tea, but is not allowed any solid food; no stimulant given. Ordered:—

R Nicotinæ, gtt. unam.

Ext. gent. q.s.

Ut fiat pil. vi. St. i. secundis horis.

The pills had a perceptible effect in lessening the spasms during the night; four turpentine enemata were given during the night; he slept for two hours.

31st: Going on favourably; breathing during the spasms very difficult; still expectorating a good deal; pulse 100. Ordered:—

R Nicotinæ, gtt. duas.

Ext. gent. q.s.

Ut fiat pil. viii. St. i. tertius horis.

An enema, consisting of leaf tobacco gr. xxx., infused in a pint of water, was ordered, five ounces at a time; also a warm bath; both the pills and enema had a good effect.

November 1st. Three drops of nicotine were ordered to be divided into the same number of pills, one to be given every third hour; slept from three to eight A.M.

2nd. The pills were repeated, also a warm bath; pulse 92.

3rd. Tobacco was ordered as before in enema; pulse 88.

4th. A castor-oil and rhubarb draught ordered; also enema of tobacco as before, and bath.

8th. Enema of tobacco as before.

9th. Nothing ordered.

10th. Enema of tobacco and a cough mixture.

14th. Enema of tobacco.

16th. Tobacco enema, gr. xx: to the pint; $\mathfrak{z}v.$ to be injected; this was the last enema given.

19th. No attack of spasms; cough better, but still has a slight rigidity of the muscles of mastication; can open his mouth about an inch.

21st. Was allowed up for the first time to-day; pulse 88. The patient has now completely recovered without much loss of flesh.

The spasms continued for a period of twenty-six days; and he was suffering for four days before admission.

The total amount of nicotine administered from October 30th to November 2nd, amounted to nine drops.

Juice Tobacco enemata were given from October 28th to November 16th, as follows:—

A larger quantity than actually required was usually ordered, to provide for repetition of the enema if the first came away without effect.

Oct. 23, 60 grs. of Tobacco infused in a pint of water, 5 oz. were injected.

SPECIAL REPORT

ON THE

TREATMENT OF CHOLERA BY VENOUS INJECTIONS.

V.

THE EPIDEMIC OF 1866.

(Continued from page 539.)

DURING the epidemic now passing away, the attempt has again been successfully made to arrest the collapse stage of cholera by the introduction of fluids into the veins. By some, simple warm water has been employed, by others, serum, defibrinated blood, and saline fluids, to which alcohol has sometimes been added. At the height of the epidemic, our "Hospital Reports" several times alluded to the cases treated upon this plan. Thus we recorded two cases treated at University College Hospital by injections of a solution of carbonate soda of the strength of twelve grains to the pint. We also described a case at the Middlesex Hospital treated by saline injections, under the care of Dr. Murchison. A more extended trial of this method was made at the Bethnal Green Cholera Hospital, of which details will be subsequently given. But, as in the two former epidemics we have described, the London Hospital has again been the scene of the fullest and most important trial of venous injections. Drs. Cobb and Little had indeed both retired from their posts at the hospital, after many years' service, but the results of their observations had favourably disposed some of their successors. Dr. Fraser, the senior physician to the hospital, who has witnessed four epidemics in various places, and had seen some of the cases we have published, recommended a renewed trial of this method, and for this purpose placed some of his cases at the disposal of Mr. L. S. Little, Assistant-Surgeon to the hospital, and son of his former colleague, Dr. Little, whose case we have reported. Dr. Fraser, in a paper contributed to the London Hospital Reports on the present epidemic, says he "is strongly impressed with the feeling that by injection through the veins lies the true means of saving life during the paroxysm of real algide cholera." It is obvious, therefore, that our report would be incomplete without an account of the cases which have produced such an impression on the mind of so experienced a physician. First of all as to the fluids employed: In two cases defibrinated blood was used. It produced no favourable change whatever. The cases were, in fact, so bad that the temporary rally did not take place, and no conclusion can be legitimately drawn from them. In two other cases serum was injected. Deep's blood was left to separate, and the serum poured off in from four to six hours. An extended trial of serum as impracticable, on account of the difficulty of having it ready at the time required. This is exemplified in the first case, in which, from there not being enough serum, it was necessary to mix it with saline fluid. Seventy ounces of this mixture were injected, but the patient was *in articulo orbis*, and no rally took place. In the other case forty ounces of pure serum produced so good an effect that the next day it was thought he would recover. He subsequently sank, his death being perhaps partially accounted

for by his age, which was sixty-four. The saline fluid tried was as follows:—Chloride of sodium, sixty grains; chloride of potassium, six grains; phosphate of soda, three grains; carbonate of soda, twenty grains; distilled water, twenty ounces.

To this fluid, in the majority of the cases, and in all the successful ones, alcohol was added in the proportions that Dr. Little had successfully used in 1849—viz., two drachms to the pint. So much for the fluids used. Now as to the operation and the means of injecting. Occasionally a vein was not visible at the bend of the elbow, but there was not often any difficulty in finding one.

Mr. Little usually exposed the vein and passed a probe under it before opening it, finding that he could then turn on the fluid, and so wash away any blood that might issue from the opening, and to enable him to see clearly the parts. This plan avoids such like risk as there may be of pushing the nozzle into the cellular tissue or along the sheath of the vein. It will be seen that the operation is as easy as that of ordinary blood-letting. At first Mr. Little used the syringe invented by his father, and of which we have already given a figure. Then in a few cases he attached an india-rubber tube furnished with a proper nozzle to a funnel, and so allowed the fluid to flow in by force of gravity. Subsequently he devised an apparatus to carry out this view with ease and certainty. As this enables the whole process to be easily carried out by one person, and provides for the fluid being kept at the proper temperature, besides allowing the operator to watch the temperature and make other observations, it is likely to be used on future occasions. We therefore add the following figure of the instrument, which is made by W. Ernst, 80 Charlotte-street, Fitzroy-square.

a vessel; b tap; c nozzle; d spirit lamp; e fastening to bed-post; f thermometer.

Mr. Little's apparatus consists essentially of a vessel (A) holding the fluid, with a spirit lamp (D) beneath it to regulate the temperature. To the tap (B) a thick india-rubber tube, four feet long is fixed, terminating in a silver nozzle (C). The apparatus can be fixed to the bed-post by the fastening (E) at about the level of the patient's head. It is then found that the nozzle being introduced into a vein at the bend of the elbow, the fluid will flow in in about ten minutes by the mere force of gravity. The apparatus actually employed by Mr. Little held forty ounces of fluid, but as more than this is often required, it would probably be more convenient to have a vessel of larger capacity, say 80 or 100 ounces.

PAPERS ON DERMATOLOGY.

No. IV.

PORRIGO.

By T. W. BELCHER, M.A., M.D. Dub.,

FELLOW, CENSOR, AND EXAMINER, KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND; PHYSICIAN TO THE DUBLIN DISPENSARY FOR SKIN DISEASES, &c.

(Continued from 13th June, 1866, page 621.)

Case 1.—B. M., a girl aged six, and lately recovered from scarlatina, from which she was partly deaf at the time of her first visit, was admitted to the Dublin Dispensary for Skin Diseases on the 10th of January, 1865. Her case may be shortly described as a well-developed one of porrigo, or favus, extending over a large part of the cranium, but being chiefly evident on the occipital hemisphere, the entire of which was covered by the disease. As the reader will find a full description of this affection in my edition of Neligan on the Skin (p. 404), and illustrative drawings of it in his Atlas (plate xv., figs. 2 and 3), I need not here recount any descriptive particulars. In the case just noted the crusts had disappeared before I saw it, and it was in the state of nearly powder described by various writers, and was accompanied by the mousy odour which is so pathognomonic of this disease. The treatment may be shortly given thus:—the scalp was first poulticed; the hair was cut off with a scissors as closely as possible; and the surface having been thus tolerably well cleaned, Hebra's tincture (described in my former papers, and in my edition of Neligan, p. 114) was freely applied to it, and repeated poultices were superadded up to the 26th of January, when the disease was evidently much better. Tincture of iodine, prepared with methylated spirit, was now applied occasionally; and cod-liver oil was taken in small doses until the 10th of February, when she was discharged cured. About two months after that date I saw her with a clean scalp, and a good, well-grown head of hair.

Case 2.—K. A., a girl aged nine, was admitted on the 14th of February, with the scalp affected much to the same extent as in the preceding case, from which however, it differed in some important particulars. The disease was of a much worse character, and was accompanied by vermin, with which the child's head was literally alive. In order to kill these, and to cure the disease, the scalp was well covered with Hebra's tincture, which at once accomplished the former purpose, and so clothed the scabs, that by diligent poulticing and the judicious use of the scissors the scalp was soon cleared off, and this was followed by the frequent application of the methylated tincture of iodine up to the 10th of March, when she was discharged cured. At the end of that month I saw her in as good condition as the preceding case. In this case the disease was said to have existed for six months previous to her first visit to me.

I have selected those two cases from a number published in the "Clinical Records" of the *Quarterly Journal* in 1865.

I know of no better or more concise description of this affection than that given by M. Hardy of Paris in his "Leçons sur les Maladies de la Peau (Part II. 2nd edition, p. 150):—

"Une affection contagieuse caractérisée par des croutes sèches, de couleur jaunâtre, présentant au début la forme de godet, et dues à la présence dans les cheveux et sur les corps d'un parasite végétal particulier, décrit sous le nom d' *achorion Schenleinii*." To take this description somewhat in detail:—the contagious character of the

disease has been proved not only by the fact that it spreads quickly in schools and in places where a sound and a diseased person may happen to sleep together; but, above all, that it has been and may be communicated by inoculation. The dry crusts (croutes sèches), and the yellowish colour (couleur jaunâtre) are not exclusively peculiar to this disease; but the *favus* or honeycomb cup (*godet*) occurs in no other skin affection, and hence is the peculiar distinguishing mark of porrigo. That it is owing to the presence of the parasite above named has been so satisfactorily shown by many observers that it may be said to be now the received opinion of the profession. For further particulars regarding this more scientific part of the question, I must again refer the reader to my edition of Neligan.

Porrigo is a rare affection in these countries; and it is very rare indeed to meet with cases of it in what we call "the better classes." Mr. Erasmus Wilson, in his large experience, only saw it twice in 3000 cases of private practice; Dr. Neligan, after long hospital and private practice, had met with but 23 cases, which he calls "a comparatively large number;" and since the Dublin Dispensary for Skin Diseases was established in 1864, I have only met there with the two cases above given. In Scotland it does not appear to be so rare. I have seen cases of it at the Glasgow Dispensary for Skin Diseases, where, among other specimens, is preserved a defunct mouse which had been affected with it. Others have noticed it attacking various animals of the lower creation; and its mousy odour in the human subject, though not referred to in Hardy's definition, is a striking coincidence, when taken in connection with the fact that the disease really does attack mice.

On the 6th of November, in the present year, Dr. Tilbury Fox exhibited to the London Pathological Society "A Microscopic Specimen of Favus from the paw of a Cat." The cat possibly contracted this disease from a mouse.

The causes of porrigo may be briefly noted. The disease is parasitic, but it requires a soil favourable for its production. This it finds in dirty, scrofulous, ill-fed children, among whom it nearly always occurs. In them it is not always confined to the scalp, and in some instances, when long continued, the patient gets an idiotic expression of countenance, and in fact the mental powers are more or less affected by it.

In one of the cases here noted pediculi were numerous. This occurs frequently in those who have a complication of this disease with a species of impetigo, or psyracrious pustule; and the pediculi are mostly confined to the occipital hemisphere.

Diagnosis.—Porrigo has been confounded with neglected chronic eczema; and, according to Hardy, with impetigo, herpes tonsuraus, porrigo decalvans, pityriasis, and psoriasis. From all these, however, a minute examination will distinguish the genuine disease, by detecting the presence of the favus, the honeycomb-shaped cup or *godet* of the French.

Prognosis.—This is a disease of serious import, not that it tends to shorten life, but its most unsightly aspect and contagious nature make it to be greatly dreaded, to say nothing of its effect on the intellect in long-continued cases. Besides, the hair follicles get destroyed, and permanent baldness is often the result. It is, however, very often cured.

Treatment.—The first thing to be done is to destroy the parasite, next to prevent its reproduction, and to this end constitutional as well as local remedies are specially adapted. In the cases here noted I have indicated what I consider the best mode of treatment, but I would not thence have it imagined that the many other modes pursued are useless. Various modes have been resorted to to remove the parasite and the results of the disease. Among these I may shortly note the barbarous application called the pitch-cap and the process of depilation. The former was nothing more than closely fitting a pitch-cap to the patient's head, and then tearing off the hair with it. The barbarity of this practice was such that death has been known to result from it. I have seen a pitch-

cap which was used in a case of porrigo, and I should never like to see one again. The process of depilation has been undoubtedly successful with some practitioners, but where it can be avoided it needs no argument to prove that it *ought* to be avoided.

The plan which I adopted in the two cases at the head of this paper combines, in my opinion, the advantages of the pitch-cap and depilation, without the shocking and cruel barbarity of the former.

With regard to depilation, I can easily conceive cases where it might be manifestly the proper mode of treatment, for in no class of diseases is special treatment for each case of more importance than in diseases of the skin. Even where two cases may be apparently similar in all respects, the treatment which may prove successful in the one may not only not be of any use in the other, but may bring the practitioner into positive disrepute with the patient's friends if unduly persevered in. Thus in two similar cases requiring constitutional treatment, arsenic alone may serve the one, and continually nauseate and half poison the other; while arsenic with quina may completely cure the second, and do no good, but rather mischief, to the first.

THIRTY-SEVEN CASES OF

ASIATIC CHOLERA, TREATED IN CORK FEVER HOSPITAL, AND HOSPITAL OF COUNTY CORK JAIL,

IN THE YEARS 1849 AND 1853, ON THE OPIATE PLAN; AND EIGHT DEATHS; EIGHT TREATED PROMISCUOUSLY AND THREE DEATHS.

By W. BEAMISH, M.D., M.R.C.S.E.,

PHYSICIAN TO FEVER HOSPITAL AND COUNTY AND CITY JAILS.

(Continued from page 485.)

JOHN McAULIFFE, *æt.* 50. Premonitory diarrhœa and vomiting for twelve hours before admission to hospital, both serous; no action of kidneys for two days; vox cholericæ; "breath," he says, "going through his ears;" breathing slow and laboured, and countenance sunk; no pulse; tongue cold; fingers and lower extremities blue and corrugated; some heat of surface. Treatment—opiate (*gr. vj.*), ext. heat, &c.; in six hours after pulse distinct (96); copious perspirations; some natural sleep; no discharges; no urine.

Eleven o'clock, P.M. Spasmodic vomiting and hiccup.

℞ Tinct. opii, gtt. xv.

Acid hydrocyanic (Scheele) M. iv.

Spt. ammon. aromat., ℥ss.

Aquæ, ℥j. ft. Haust. 4ta q̄. Hora Sumendis.

Took three draughts; kidneys acted on fourth day; recovered; no fever.

John Collins, *æt.* 35. Premonitory diarrhœa and vomiting (greenish water) for five days before admission; kidneys acting; voice tolerable; respiration and countenance tolerably natural; skin cold but not livid. Treatment—Pulv. opii, *gr. iij.* Recovery in two days; no fever.

Johanna Hackett, *æt.* 44. Hopeless on admission. Premonitory diarrhœa and vomiting for forty-eight hours before admission (serous); so frequent, could not say how often; no action of kidneys for twelve hours; voice inaudible; respiration laboured and slow; no pulse; tongue cold; eyes sunk; skin cold and livid. Treatment—Haust. tinct. opii, ℥j., ext. heat, sinapisms, &c. In two hours and a half after, pulse distinct in both wrists; surface warm; no discharges; but sunk in twelve hours after, sensible to the last.

William Leader, *æt.* 24. Premonitory diarrhœa and vomiting (serous and solid curds) for twenty-four hours before admission; kidneys acting; voice feeble; pulse 60

and feeble; tongue foul, and abdomen full; skin rather warm.

℞ Ol. Ricini, ℥j. c. trœ. opii, gtt. xxv.; stupes, &c.

Serous vomiting continued in great quantity; got pil opii, No. 2, and Haust. tinct. of opii, ℥j. (*gr. vj.*). Next day well; no fever.

Catherine Hogan, *æt.* 60. Premonitory diarrhœa and vomiting twelve hours before admission very frequent (serous); kidneys acting; voice feeble; pulse distinct; surface cold; got pil opii No. 2, and Haust. tinct. opii, ℥j. (*gr. vj.*). Recovery on second day; no fever.

Bess Horrogan, *æt.* 40. Had been in hospital; recovering from dysentery and ran into cholera. Discharges like barley water; vomiting, character of first serous, second pure green, third brick dust. No action of kidneys for two days before admission; voice feeble; respiration oppressed and anxious; countenance sunk; pulse very thready; tongue cold; eyes sunk; skin inclined to be cold and bluish; says, "her voice is going through her ears." Treatment—opiate, dose, *gr. x.* external heat and stimulants, &c. Profuse perspiration shortly after; discharges checked; pulse 120, and strong; kidneys acted on fourth day; next day required enema amyli, c. t. opii, ℥j. Recovery fourth day; no fever.

Johanna Murphy, *æt.* 28. Diarrhœa and vomiting for one day (wheyish); no action from kidneys for eight hours; voice almost inaudible; respiration laboured, slow, and spasmodic; countenance sunk; pulse scarcely perceptible; tongue cold, skin cold, clammy, and inclined to be livid; cramps very troublesome. Treatment—opiate, dose, *gr. xij.*; towards night complained of "want of sleep," and got *gr. xxv. trœ. opii*, which had the desired effect. Kidneys acted on fourth day. Recovered; no narcotism; no fever.

A. Thornhill, *æt.* 20. Diarrhœa and vomiting for four or five hours (rice water); no action from kidneys, for how long could not ascertain; voice whispering; respiration low and sighing; pulse scarcely perceptible; tongue cold; eyes sunk; skin cold and clammy; cramps very troublesome; kidneys acted three days after admission. Treatment—opiate, dose *gr. viij.*; in six hours after required enema amyli, c. trœ. opii, ℥j., acct. plumbi. *gr. x.*; in eight hours after required Haust. opii, ℥j. in brandy and water. Recovered on fourth day; no fever.

Daniel Sheehan, *æt.* 22. Diarrhœa and vomiting (rice-water) about three days; no action of kidneys for forty-eight hours before admission; voice very low; respiration very slow; countenance sunk; pulse scarcely perceptible; tongue cold; eyes sunk; skin cold, clammy, and livid; cramps. Treatment—Opiate, dose *gr. xij.* No symptom of cholera after, but was under influence of opium; recovery on third day; kidneys acted on third day.

Edward Roche, *æt.* 22. Diarrhœa and vomiting for four hours (rice-water); kidneys acting; voice inaudible; respiration slow and laboured; pulse scarcely perceptible; tongue cold; eyes sunk; skin cold, clammy, and livid; cramps. Treatment—Opiate, dose *gr. vj.* Recovered; no fever.

James Regan, *æt.* 26. Diarrhœa and vomiting for an hour (rice water); no action of kidneys for twelve hours; voice feeble; respiration remarkably slow; pulse fifty-two, and very thready; tongue cold; skin cold and clammy. Treatment—Opiate, dose *gr. viij.* Recovered; no fever.

Mary Regan, *æt.* 37. Diarrhœa and vomiting for about eight days (rice-water), since admission very frequent; no action of kidneys for twelve hours; voice almost inaudible; respiration very slow; countenance sunk; pulse very thready; tongue cold; skin cold, clammy, and bluish; no cramps. Treatment—Opiate, dose *gr. vj.* Reaction in two hours; recovery in three days; no fever.

M. Lehane, *æt.* 35. Diarrhœa and vomiting (serous) for a week, more or less; no action of kidneys for nine hours; voice feeble; respiration slow; countenance sunk; pulse very thready; tongue cold; skin cold, clammy, and blue; no cramps. Treatment—Opiate, dose *gr. vj.*, and

gr. ij. the day after. Recovered; no fever; kidneys acted on second day.

Pat. Kinnealy, æt. 12. Diarrhea and vomiting (serous) for twelve hours; no action of kidneys for forty-eight hours; voice inaudible; pulse indistinct; skin cold and clammy; no cramps. Treatment—Enema amyli c., t. opii ʒ, external heat, &c. Death in four days.

Eliza White, æt. 17. Diarrhea and vomiting (rice-water) for about five days; no action from kidneys for twenty-four hours; voice hoarse and feeble; respiration and countenance natural; pulse very feeble; skin cold. Treatment—Opiate, dose gr. iiii. Recovery on second day; no fever.

Denis Mullan, æt. 40. Diarrhea and vomiting for six hours before admission (serous); no action from kidneys for four days; voice very hoarse and feeble; respiration slow and sighing; great noise in ears; pulse very thready; tongue cold and breath cold; skin cold and clammy; face and hands blue. Treatment—Opiate, dose gr. viij. Purgings checked; recovery on fourth day; no fever.

Mary Buckley, æt. 20. Diarrhea and vomiting most of the night (rice-water); action of kidneys could not be ascertained; voice very feeble; respiration slow; cramps very bad; pulse scarcely perceptible; tongue cold; skin cold, blue, and clammy. Treatment—Opiate gr. vj. at once and gr. ij. at night. Died within twenty-four hours.

Bridget Reilly—Diarrhea and vomiting for twenty-four hours (serous); no action of kidneys for two days; voice feeble; respiration slow; countenance sunk; pulse perceptible; tongue natural; skin warm, but lower extremities very cold and livid. Treatment—Opiate, dose gr. vj. Reaction in about three hours; recovery on third day; no fever.

Cath. Regan. Diarrhea and vomiting three or four days—the former gruelly; the latter, first serous, secondly sea-green water; no action from kidneys for twenty-four hours; voice feeble; respiration and countenance natural; pulse very feeble; skin warm, but face cold and clammy. Treatment—Opiate, first dose, gr. iiii.; day after R hyd. sub. gr. v., pulv. opii. gr. j. f. t. pil. Recovery on third day; no fever.

Joha. Brady, æt. 30. Hopeless in fever when cholera set in. Diarrhea every minute (serous), no vomiting; no action of kidneys for forty-eight hours; voice whispering; respiration very slow; countenance sunk and livid; pulse scarcely perceptible; tongue cold; skin cold, clammy, and blue; no cramps. Treatment—Opiate, dose gr. ij., external heat, and stimulants. Death in four days; no reaction all through.

Pat. Ahern, æt. 24. Diarrhea and vomiting (serous) for some hours before admission; kidneys acting; voice feeble; respiration oppressed; pulse distinct, but very feeble; respiration laboured; pulse feeble; tongue natural; skin cold and livid. Treatment—Tinct. opii ʒj., external heat, &c. Well in six hours; no fever.

Mary Cotter, æt. 31. Diarrhea and vomiting (serous) for twelve hours; kidneys acting; voice feeble; tongue cold; skin cold and livid; noise in ears; cramps. Treatment—Træ. opii ʒj. Discharges ceased; pulse eighty and full; profuse perspiration; recovering; no fever.

Portuguese sailor, dying on admission. Diarrhea and vomiting (frequent and serous) for eighteen hours before admission; no action from kidneys, could not say for how long; voice feeble; respiration slow; no pulse; tongue cold; countenance sunk; skin cold, blue; cramps and hiccup. Treatment—Pil. opii No. 2, and Haust. opii ʒj.; in some hours after ext. heat, &c. Died in eighteen hours, and conscious to the last.

Bridget Leahy, æt. 30. Diarrhea and vomiting for two days—the first blackish water, second gruelly matter; no action from kidneys for four days; voice feeble; pulse 70 and feeble; thinks "something has got into her ears"; body and extremities warm, but face cold and clammy. Treatment—First dose pulv. opii gr. v.; second, gr. iiii., and starch enemata. Recovery on fourth day; no fever.

—Burke, debtor. Diarrhea and vomiting (purely serous) for eight hours; no action of kidneys; voice almost inaudible; respiration very slow; countenance sunk; pulse scarcely to be felt; tongue cold; skin cold, blue, and clammy. Treatment—Opiate, dose gr. iv., external heat. Death in six hours, and conscious to the last.

Ml. Sherlock, æt. 4 years. Diarrhea and vomiting (rice-water); no action of kidneys for twenty-four hours; voice sharp and feeble; countenance sunk; pulse perceptible, but very feeble; tongue cold; skin cold and clammy. Treatment—Opiate, dose træ, opii gts. xv., enema amylic, træ opii gts. x., wine, whey, &c. Recovery on second day.

Mary Sullivan, æt. 48. Premonitory diarrhea and vomiting for two days before admission (serous) incessant; none after, being drained; no action of kidneys for two days; voice inaudible; respiration laboured; great præcordial oppression; no pulse; tongue icy cold; countenance sunk; skin cold and shrivelled. Treatment—Pil. opii No. 2 (gr. ij.), external heat, stimulants, &c.

In four hours after temperature of body improved, but no pulse; slight return of serous purging R Haust. tinct. opii ʒij. Death in twelve hours.

Julia Reardon, æt. 60. Premonitory diarrhea and vomiting (serous) about a week before admission; no action of kidneys for three days; voice, respiration, and countenance choleraic; pulse very feeble; skin cold; cramps. Treatment—Opiate, dose gr. vj., external heat, &c.; discharges checked and more natural; surface warm and perspiring; six hours after enema amyli c. tinct. opii ʒj. Recovered; no fever.

Bridget Leahy, æt. 30. Diarrhea and vomiting (the former gruelly, the latter serous) for two days before admission; no action of kidneys for three days; voice feeble; respiration natural; pulse very feeble, 100, and intermittent; tongue natural; noise in ears; skin inclined to be cold. Treatment—Opiate, dose gr. vj., external heat, sinapisms, &c.; discharges ceased; next day abdomen distended with flatus; got enema terebinth, c. tinct. assaætida; bowels moved so often got pulv. opii gr. ii. Recovered; no fever. This woman had cholera three weeks before.

T. Key Rogan, æt. 50. Diarrhea and vomiting (serous) for six hours; no action of kidneys for forty-eight hours; voice inaudible; respiration very slow; countenance sunk; pulse scarcely perceptible; tongue cold; noise in ears; skin cold, blue, clammy, and corrugated. Treatment—Opiate, dose gr. vj., external heat, &c. Death in nineteen hours; no reaction from beginning.

T. Murphy, æt. 45. Diarrhea and vomiting (serous) six hours before admission; no action of kidneys for forty-eight hours; voice inaudible; respiration very slow; countenance sunk; pulse scarcely perceptible; tongue cold; noise in ears; skin cold, blue, and corrugated. Treatment—Opiate, dose gr. vj., external heat, &c. Recovery on the fourth day; no fever.

Dl. Magrath, æt. 50. Diarrhea and vomiting (serous) for seven hours before admission; kidneys acting; voice feeble; respiration laboured; pulse forty, and feeble; tongue cold; skin cold and clammy; tinct. opii ʒj. (gr. iv.), external heat, &c. Discharges ceased. Recovery; no fever.

Mary Roche, æt. 30. Diarrhea and vomiting for two days (the former gruelly, the latter rice-water); no action of kidneys for three days; voice feeble; respiration natural; countenance sunk; skin cold; no cramps. Treatment—Pil. opii No. 2, (gr. ij.), external heat, &c. Vomiting checked; diarrhea continued; abdomen so much distended got enema terebinth; bowels moved so frequently (rice-water), got pil. opii No. 4 (gr. iv.), and afterwards required enema c. tinct. opii ʒj. Recovery on the fourth day; no fever.

Julia M'Carthy, æt. 30. Diarrhea and vomiting for twelve hours, both gruelly at first; afterwards diarrhea (serous), very frequent; no action of kidneys for two days; voice feeble; respiration slow; pulse very feeble; tongue natural; skin inclined to be cold; cramps in hands

very severe; great noise in ears. Treatment—Opiate, dose gr. viii., external heat, stimulants, &c. Discharges not checked for twelve hours; got enema, tinct. opii ʒj.; improved in every way after. Recovery on the fourth day.

Bessy Lyons, æt. 30. Diarrhœa and vomiting for three days, first serous, afterwards green water; no action of kidneys for three days; voice feeble; pulse distinct but thready; skin cold; cramps. Treatment—Opiate, dose gr. vj., stimulants and external heat; bowels checked, vomiting continues; enema c tinct. opii ʒij. Recovery on the fourth day.

Cor. M'Carthy, æt. 48. Diarrhœa and vomiting (serous) for two days; no action of kidneys for twenty-four hours; voice very feeble; tongue coldish; skin cold; no cramps. Treatment—Opiate, dose gr. vj., reaction in four hours; kidneys acted on the third day. Recovery on the fourth day.

Julia M'Carthy, æt. 40. Diarrhœa and vomiting for three days (serous); no action of kidneys for forty-eight hours; voice very feeble; countenance sunk, deaf, and noise in ears; pulse very feeble; skin inclined to be cold; no cramps. Treatment—Opiate, dose gr. iv.; external heat, stimulants, &c. Discharges checked; but required enema c tinct. opii ʒij.; kidneys acted on the fourth day. Recovery on the fifth day.

EIGHT CASES—PROMISCUOUS TREATMENT—AND THREE DEATHS.

DI. Shayhane, æt. 30. Diarrhœa and vomiting (purely serous); no action of kidneys for forty-eight hours; voice inaudible; respiration very slow, and sighing, with pain under right breast; countenance sunk; pulse not to be felt; tongue icy cold; skin cold, clammy, and blue; cramps very severe. Treatment—Saline (Dr. Stevens'), external heat, &c. Death in twenty-four hours.

Cath. Casey, æt. 35. Diarrhœa and vomiting for about a week (waterish); no action from kidneys for two days; voice feeble; respiration slow; pulse very feeble; skin cold and clammy; cramps troublesome. ʒ ol. Ricini ʒj. trœ opii gr. xxv. aq. m. pip. ʒiss., stomach being full and distended. Recovery on the second day; no fever.

Eliza Nowlan, æt. 25. Diarrhœa and vomiting for the previous night (waterish); abdomen distended; no action of kidneys for twenty-four hours; voice feeble; pulse feeble at forty; upper and lower extremities cold; cramps very bad. ʒ ol. Ricini ʒj. c. tinct. opii gr. xxv.; foment abdomen, external heat, &c. Recovery on the third day; no fever.

Chas. Murphy, æt. 16. Diarrhœa and vomiting (profuse and serous) for two days; no action from kidneys for twenty-four hours; voice feeble; pulse feeble; tongue natural; skin natural; cramps in fingers and legs. Treatment—R mist. magnesiæ c spt.ammon. aromat. et tinct. opii ʒj. ad ʒviii. Required towards night ol. Ricini ʒj. c. trœ opii gtt. xx.; vomiting relieved. Recovery on the third day.

Eliza Bateman, æt. 30. Bowels confined, and abdomen distended and hard; vomiting frequently (serous); no action of kidneys for twenty-six hours; voice very feeble; pulse sixty and feeble; skin moist and rather warm; cramps in hands and feet; ʒ enema terebinth; stimulants and external heat; ʒ hyd. sub. gr. iij. pulv. opii gr. ¼ ft. pil. Recovered.

Jno. Leary, æt. 12. Diarrhœa and vomiting (serous) for five hours, no action of kidneys for twenty-four hours; voice very feeble; pulse sixty, and very feeble; tongue icy cold; skin blue, cold, and cramps. Treatment—Saline, external heat, &c. Death in sixteen hours.

Honora Shea, æt. 17. Diarrhœa and vomiting for six hours and a half (serous); no action from kidneys for could not say how long; voice feeble; pulse eighty, and feeble; tongue natural; skin warm; abdomen full; ʒ ol. Ricini ʒj. c. trœ opii gtt. xxx.; external heat, &c.; required enema commune et hyd. sub. gr. ij. pulv. opii gr. ¼. Recovered; no fever.

Jane Mercer, æt. 30. Diarrhœa and vomiting (serous) frequent before admission, but worse after; no action of kidneys for three days; voice feeble; respiration slow; no pulse; tongue cold; skin cold and livid, and pain at epigastrium. Treatment—saline, sinapisms, external heat, &c. Death in two hours after admission.

CONTRIBUTIONS

TO THE

PATHOLOGY AND TREATMENT OF CHOLERA.

SOME CASES SUCCESSFULLY TREATED ON THE DIURETIC PLAN.

By AUSTIN MELDON, L.K.Q.C.P., L.R.C.S.I., L.M.,

ASSISTANT MEDICAL OFFICER TO THE SOUTH CITY DISPENSARY, CANAL-STREET, &c.

(Continued from page 539.)

Mrs. HICKEY, 8, Great Clarence-street, ætat 40, was attacked on the evening of Sunday, the 11th Nov., with severe pains in the abdominal region, accompanied with violent purging and reaching, and the other usual symptoms of cholera. These continued without abatement until two A.M., when I was summoned to attend. I found the patient in complete collapse, cold, and pulseless; the lips and skin were almost black, the bed and floor were strewed with the rice-water evacuations, the vomited matter, which lay in a vessel beside the bed, was of a brownish colour. The facies cholericæ was well marked, the patient lying quite unconscious of what was passing around her. Occasionally the cramps roused her from this stupor. The functions of the kidneys were completely suspended; no urine being passed. I ordered a large mustard and linseed meal poultice to be placed over the abdomen, a little burned brandy mixed with soda water to be constantly administered; her body to be swathed in warm blankets; hot jars to be applied to the feet and legs; also the following:—

ʒ Plumbi acetatis, gr. xxiv.

Acedi aceticæ, ʒj.

Morphiæ acetatis, gr. i.

Spiritus juniperi, ʒj.

Aquæ camphoræ, ad ʒviii.

M. Fiat mist. Two spoonfuls every hour.

Also

ʒ Spiritus chloroformi, ʒj.

— menthæ peperitæ, ʒi.

Tincturæ capsici, ʒij.

Liquoris Hoffmanni, ʒiij.

Spiritus ætheris nitrosi, ʒiv.

Aquæ camphoræ, ad ʒviii.

A dessertspoonful every ten minutes.

12th, 8 A.M. Passed a little urine; skin warm, and has almost resumed its natural colour; purging somewhat less; vomiting continues; cramps less severe.

Six P.M. Skin perspiring; vomiting and purging greatly abated; she has passed a large quantity of urine.

13th. Condition greatly improved; vomiting and purging almost ceased; no cramps.

14th and 15th. Remained free from choleraic symptoms; ordered her mist. quiniæ sulphatis.

16th. Was sent for at one A.M.; vomiting and purging had returned with increased violence; she thinks it was the quinine mixture that caused the relapse; it was accordingly discontinued, and the mist. plumbi acetat. et junip. ordered to be recommenced.

Eight A.M. Purging ceased; vomiting continues; the matter throwing off being of a dark green colour. One P.M. Urine freely passed; vomiting continues. Eleven P.M. Ordered creasote mixture.

17th, eight A.M. Vomiting continues; to take bismuth mixture. Ten P.M. Still vomiting; ordered burned brandy and soda water well iced, also a draught containing a full dose of laudanum.

18th. Shortly after taking the draught she fell asleep, and did not awake until this morning; no vomiting has since occurred. From this day she improved rapidly, and is now quite well.

Hickey, 8 Clarence-street, *ætat* 16, was attacked with cholera on the morning of the 18th. His mother was just recovering from a bad attack of the same disease. On the day previous he had diarrhœa, for which he had taken some chalk mixture. I saw him a few hours after the symptoms of cholera were developed, and directed the *mistura acetat plumbi et juniperi* to be taken. For twenty-four hours the skin and kidneys obstinately refused to act, meanwhile he was fast sinking into collapse. On the night of the 21st I found him in the following state: Pulse very feeble; skin cold, dry, and gradually assuming a dusky appearance; the lips were quite purple, and the voice had assumed the characteristic change. He complained of great pain in the epigastric region, and also in the head and back of the neck; the vomiting and purging were very severe, also the cramps. As during the previous twenty-four hours every effort to compel the skin and kidneys to throw off the choleric virus had been unavailing, as a last chance I ordered him to take one tablespoonful of the mixture every ten minutes. After the sixth dose he passed about a pint of high-coloured urine, and almost immediately a "change for the better set in." I found him next morning greatly improved; the vomiting and purging had completely ceased. He had passed urine six or seven times during the night, and had slept a good deal. From this date he rapidly improved, and in a few days was pronounced convalescent.

Kate Hannon, 5, Baggot-court, *ætat* 15, previously healthy, was seized on Monday, the 19th, with violent pain in the abdomen, soon followed by vomiting and purging. She was seen by the medical officer on duty, who ordered her pills of acetate of lead and opium. Next morning, when she came under my care, I found her in the following state:—Pulse almost imperceptible; skin cold and dry; vomiting and purging constant; cramps very severe; in fact she was fast falling into collapse; no urine had been voided during the previous night; the *vox cholericæ* was well marked, and the appearance of the girl was very characteristic of the disease, I ordered her a tablespoonful of the *mist. plumbi acetat. et junip.* every half hour. When I saw her at noon she was greatly improved, and urine had been secreted in considerable quantity. She continued improving rapidly until the night of the 21st, when she became very ill, and before I saw her in the morning had almost passed into collapse. She was cold and pulseless, severely cramped and purged, and vomiting constantly. I ordered her a dessertspoonful of the stimulating mixture every ten minutes, and two tablespoonfuls of the *mist. plumbi et junip.* every hour.

At four P.M. she seemed somewhat improved, but as the skin was dry, and no urine had been voided, I had little hope of a favourable result. The bad symptoms continued until ten P.M., when I administered a large dose of opium and camphor. She passed a considerable amount of urine about twelve o'clock, and immediately afterwards she fell into an uneasy sleep, from which, however, she awoke in the morning with all the symptoms considerably mitigated. From this date she rapidly improved, and in a few days was pronounced convalescent. A few days after her recovery, the father and sister died from cholera; at present the second sister and mother are in hospital with the same dreadful disease.

LEGAL INTELLIGENCE.

MACKENNA *v.* PARKES.

THIS bill was filed for a partnership account, and a return of the whole or part of £1250 deposit, given partly in bills and partly in cash, under these circumstances:—The plaintiff, Dr. Mackenna, entered into partnership as a medical

practitioner with Dr. Parkes, of Great Marlborough-street, and the agreement thus come to embodied the usual terms, and also there was a clause that Dr. Parkes would introduce the plaintiff to his patients. Dr. Parkes was dead, and his widow and executrix, better known as Amy Sedgwick, sued the plaintiff on the bills, and this suit was also to restrain that action. It was not in dispute at the time of the commencement of the partnership. Dr. Parkes was suffering from "Bright's disease;" he was told so by several medical friends, and was in extremely low spirits in consequence, and went to Margate and elsewhere for his health but ultimately died of apoplexy. One material question was whether the plaintiff knew this fact, which he said he did not. He also charged that Dr. Parkes had left town for a long period, which the defendant denied. Also that he had never been introduced to the patients as agreed upon, only twelve or fourteen being introduced to him out of more than two hundred. This was admitted, but it was said that a circular written by Dr. Parkes was given to the plaintiff to use, and that it had been sent round to several clubs which Dr. Parkes attended. Moreover, that the mode of introducing patients to a new partner was from time to time, as occasion arose. A Mr. Wilson, who managed the transaction, also swore that he did not know of Dr. Parkes' disease.

Mr. Glasse and Mr. Lindley appeared for the plaintiff; Mr. Baily and Mr. W. W. Cooper for the defendant.

Mr. Glasse was heard in reply.

His Honour, after stating the facts, said that one most important element in the consideration for the £1250 was the introduction to patients, and it clearly appeared that out of between 300 and 400, producing £1400 a year, only a very limited number were actually introduced. Then came the question of the state of Dr. Parkes' health. It clearly appeared that he knew and felt deeply that he was afflicted by Bright's disease, an ailment which he might die of very shortly, or which he might have for years and still live. It was clear that the person who managed the partnership transaction did not know it; and then came the question whether the plaintiff knew it. Dr. Parkes' assistant swore that he told him, and the plaintiff most positively denied it. His Honour thought that the plaintiff did not know it when the partnership was formed, but did know it in August following, and probably did not insist on his rights, because as a medical man he considered Dr. Parkes might live for years. There must be an account, and the plaintiff must be debited with £600, and credited with a reasonable portion of the £1250. No costs to either side.

THE MEDICAL SOCIETY OF LONDON.

MONDAY, NOVEMBER 26TH, 1866.

A PAPER was read by Dr. TILBURY FOX

ON THE STUDY OF DERMATOLOGY IN ENGLAND.

In it reference was, first of all, made to the opinion pronounced unanimously by the Press and the Profession, that more ignorance prevails in skin matters than in any other branch of medicine; and the author then attempted to show that no opportunity exists in England by which a man who aims to prosecute the study of cutaneous medicine, can do so with any prospect of satisfactory success, that the continental schools present a very marked contrast in this respect, and that all recent advances in dermal pathology have been made by the labours of continental physicians. It appears that in none of the London Hospitals is there a ward set apart for skin diseases. At none, save University College, is there any special course of lectures on the subject in conjunction with clinical demonstrations. He then referred to errors of, and the general abstinence from, diagnosis, to the unsatisfactory amount of attention bestowed upon skin diseases in the out-patients' departments of our large hospitals, observing, "Non-made men go abroad to learn what they fail to get in England." It is impossible to avoid the censure which we cast upon ourselves by that one fact—that so sadly is the study, and so little the opportunity, afforded even the most zealous student of acquiring really a moderate amount of knowledge of skin diseases, that he finds it not only worth his while, but necessary almost to his credit, that he undergo the special expense and trouble of a residence abroad, to make good the deficiency. After sketch-

ing the provisions made abroad to this end, the author defended cutaneous medicine from the charge of semi-quackism and superficiality that had been made against it, pointing out that no doubt dermatologists had brought discredit upon themselves, because they had been guided solely by self-interest and empiricism, and had never brought the facts of general pathology to bear upon the subject to which they devoted their attention—had never studied it with a true love for science. He then traced its connection with some of the most profound questions in medicine, entering into the relation of carbuncle and diabetes, and zoster and nerve change, for illustration.

The author then went into the question of the contrast presented by the diseases of the continent and those of our own country. "English skin diseases and those of foreign climes resemble each other up to a certain point, but then diverge and exhibit peculiarities in each case—differences that will not permit the same treatment to be alike applicable to the two cases." He related his experience gained in Paris, Vienna, Egypt, and Syria; referring to lichen ruber, lichen scrofulosus, eczema marginatum, scabies, favus rufoleuca notha, scarlatina, pityriasis rubra, molluscum, merphœa, lupus, rupia, and other affections, and pointing out the contrast between these diseases as seen abroad and in our own country, and the danger of accepting foreign teaching and descriptions as accurate representations or guides for us, and expressed the regret that at our medical colleges there are no authorities to which the student and practitioner can look for the prevention of error in this particular, and he showed how writers had fallen into error from a want of knowledge on this point.

After criticising the empiricism of treatment, local and general, especially in reference to arsenic, the author concluded thus—"No one, I suppose, will defend the position in which cutaneous medicine stands at the present moment; no one will deny that we are in no little danger of admitting a considerable influence for error by the wholesale and blind acceptance of foreign views and opinions, which (most valuable in themselves) are not wholly conversant with the experience of our own country, that the establishment of one special clinique would be acceptable to the student and the practitioner; that the public has much reason to censure us for neglecting the study and treatment of a class of evils which affect the poor very materially, which enable him sufficiently to teach him what want is, but yet in the majority of cases scarcely to entitle him to active relief; and lastly, no one will be severe upon me because I have to the best of my ability attempted a somewhat unpalatable task, to give a glance at our shortcomings in the matter of dermatology, to point out some dangers which menace it, and to defend it from unjust criticism."

Dr. Camps, Dr. Symes Thompson, Dr. Head, Dr. Abbott Smith, Mr. Spencer Watson, and Dr. Rogers, took part in the discussion which followed.

Reviews.

ON EPILEPSY, HYSTERIA, AND ATAXY. Three Lectures. By JULIUS ALTHAUS, M.D., M.R.C.P., Physician to the London Infirmary for Epilepsy and Paralysis, &c. Pp. 126. London: Churchill and Sons. 1866.

THESE Lectures are not intended to represent a complete treatise on the three diseases of which they treat, but to give Dr. Althaus' views on some of the more important points in their pathology and treatment, and on which he conceives that much misconception has hitherto prevailed. We do not find, however, that in the lectures on Epilepsy and Hysteria there is much novelty, and although Dr. Althaus is more hopeful of a cure in the former disease, than many other authorities, he does not explain fully the therapeutic measures which he has found generally successful. The lecture on Ataxy is a very good *resumé* of what is known as to the pathology and treatment of this disease, which though lately described, particularly by Dr. Duchenne of Boulogne, has long been known under the name of *tabes dorsalis*. It is a disease of middle life, is far more common in males than in females, and it is attributed, though perhaps on insufficient grounds, to sexual excesses. Its pathology is supposed to consist of a wasting of the posterior columns of the spinal cord, and its distinguishing feature is

a want of co-ordination in the voluntary movements, and hence the name ataxy. Dr. Althaus thinks that the most valuable remedy in this disease is the nitrate of silver administered in small doses and with due precautions. This little work of Dr. Althaus is very well written and contains a great amount of useful information.

GUY'S HOSPITAL REPORTS. Edited by C. HILTON FOGGE, M.D., and ARTHUR E. DURHAM. Third series. Vol. XII. Pp. 684. London: Churchill and Sons. 1866.

THE present volume of these reports, which have been offered to the profession from year to year for a considerable period, amply testifies to the zeal, industry, energy, and learning of the staff of Guy's Hospital. The bulk of the book is, we believe, greater than that of any of its predecessors, and the value of the contents is in no degree inferior. They comprise, in fact, an immense mass of facts gathered together from the great storehouse of pathology at the disposal of the writers, and they constitute a most valuable and welcome addition to our existing knowledge in practical medicine, surgery, midwifery, and toxicology. If in these reports the domain of therapeutics appears to be less cultivated than those of the other branches of medical science, the circumstance may be readily accounted for by the present tendency of medical inquiry, which seeks rather to ascertain how much may be effected by the powers of nature in the cure of disease, than to trust to the administration of drugs.

The papers are twenty-five in number, and some of them are so lengthy and elaborate as almost to form treatises in themselves, such as for instance the paper on the pathology of some of the diseases of the nervous system by Dr. Wilks, who ranges over the whole field of cerebral and spinal disease, and that on diseases of the retina by Mr. C. Baker, who offers an exhaustive memoir not only on the morbid conditions of the nervous tunic of the eye, but also on the functional disturbances of this membrane caused by diabetic conditions of the body in general, or the operation of toxic or medicinal agents. Other papers again are portions of series which are in course of publication in the annual reports, as for instance the contributions to the physiology of Binocular Vision, by Mr. Joseph Towne; the contributions to the Practical Surgery of New Growths or Tumours, by Mr. John Birkett; and the memoirs entitled Select Clinical Reports, by the lamented Dr. Barlow, who has so lately passed away amidst the regrets of his colleagues and the profession in general. Among the serial papers may also be enumerated those on the treatment of Acute Rheumatism, of which three appear (including that of Dr. Barlow) in the present volume. The other two are respectively by Dr. Owen Rees, who still advocates the employment of lemon juice as superior to any other mode of medication; and by Dr. H. G. Sutton, who, recording the practice of Dr. Gull, maintained the superiority of the expectant system, under which many recoveries are recorded, and few untoward results (unless we except one case of sudden death, apparently from syncope) are admitted. Among the other papers, we find an interesting one on Hydrophobia, by Mr. J. Cooper Forster, a most elaborate one on the Application of Physiological Tests for certain organic poisons, and especially Digitaline, by Dr. Hilton Fogge, and Dr. T. Stevenson; a practical one by Mr. Cock on the means to be adopted for establishing a communication between the bladder and the exterior of the body, when the urethra has become impermeable; and one equally practical by Dr. Braxton Hicks, on Amputation of the Cervix Uteri, and other methods of local treatment in cases of malignant disease of the uterus and vagina. Among the single cases most deserving of notice, we may instance the case of Intermittent Hæmatinuria, with remarks by Dr. Gull; that of Abdominal Tumours by Dr. Habershon; and that illustrating the Spontaneous Cure of Aneurism of the Aorta by Dr. Moxon. In this latter case the cure of the aneurism appears to have been effected by the wasting caused by an extensive cancerous affection in another part of the body, and hence Dr. Moxon argues in favour of the now disused treatment proposed in internal aneurism by Valsalva. Space alone prevents us from alluding to several other very meritorious papers and monographs, all of which, however, are well worthy of perusal, and we may state generally of the volume before us, that it fully upholds the reputation of Guy's Hospital as one of the leading medical schools in the metropolis.

Correspondence.

THE YELLOW FEVER ON BOARD THE *ATRATO*, AND THE ABSURDITY OF QUARANTINE RESTRICTIONS IN CONNECTION THEREWITH.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The Royal Mail Ships have now steamed into the Southampton Waters for more than twenty years without the slightest prejudice to the health of the inhabitants.

In 1851, and for several years afterwards, yellow fever raged with dreadful effect in the West Indies, and many of the steamers arrived at seasons favourable to the propagation of the disease, if amenable to personal communication, but nothing of the kind occurred, or is likely to occur; and, notwithstanding the disease has been incomparably less virulent in the *Atrato* than it was on board the *Orinoco*, *La Plata*, and other vessels some years ago, yet now with a temperature, in which yellow fever has not been known to exist, the world has been startled and terrified by learning that some dreadfully contagious disease has broken out, about which there should be no doubt, as the unfortunate passengers and crew have been cooped up, and actually put in quarantine at the Motherbank, although not a single passenger had suffered during the voyage! How preposterous a proceeding!

Any common-sense person must be amazed that the passengers and crew were not removed with all speed from the floating pest-house wherein the disease had maintained itself for some weeks. The risk incurred by their unnecessary detention, in a vessel demonstrated to be unwholesome, for a single hour, can only be regarded as a piece of refined cruelty.

1866, the date of this stultifying act, will not be soon forgotten. Whether attributable to the Lords of the Privy Council having unfortunately appointed as their medical advisers meddlesome and partially-informed men, or not, it is unquestionably a retrograde policy, and, in whatever aspect viewed, calculated to produce inconceivable mischief.

Who that has been obliged, even occasionally, to breathe the atmosphere and notice other conditions unfavourable to health in the *steerage of ships generally*, but has almost felt ashamed of the age in which we live? There are filthy houses afloat as well as on shore, and, if more rational measures were enforced, in relation to the seaworthiness, as well as healthfulness, of our marine, by the appointment of efficient officers, an inestimable blessing would be conferred on the brave tars of Britain.

Dr. Buchanan, in reference to an outbreak of yellow fever at Swansea, remarks "that there were twelve centres from whence the disease, if it had been communicable from person to person, had the opportunity of spreading, and many of these localities were perfectly adapted for the spread of contagious diseases; yet in no *single* instance, out of all these, did any person get yellow fever, or any disease simulating it."

"The conclusion, then, appears indisputable, that if the fever was communicable at all by personal contagion, it was so only in an extremely feeble degree. If it had behaved like any of the (more) contagious fevers, such as *small-pox*, *measles*, *typhus*, or *relapsing fever*, it is quite certain that no such account as this (the foregoing) could have been given." Old West Indians, and those medical men who have practised in yellow fever districts, ridicule the contagion theory as worse than absurd.

The despotism of General Butler's rule at New Orleans, turned to the good purpose of sanitary improvements, has accomplished what sanitarians expected in arresting the frequent autumnal ravages of the yellow fever in that city.

Again, by slow degrees, ague, or intermittent fever, and to a great extent remittent fever (simply ague intensified and yellow fever in its mildest form), have been, in the course of only two or three generations, in our own country, by the improved tillage of our soil alone, rendered incapable of maintaining their source of origin. Within my own experience ague prevailed in large districts in this country where the disease is now almost unknown.

The best pathologists regard ague and yellow fever as identical in type. The miasma which produces the one or the other has ever equally eluded the most delicate researches of the physicist or chemist—but that either was capable of being propagated by personal communication has been again

and again disproved by the most painstaking investigators, and supported by such evidence as logical minds cannot fail to accept.—I am, sir, yours obediently,

EDWIN HEARNE, M.B., LONDON,
F.R.C.S., ENG.

Southampton, November 22nd, 1866.

* * This letter, to which attention was drawn in our editorial columns last week, was unavoidably omitted for want of space.—Ed.

TOXICOLOGICAL DISCREPANCIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the middle of September last a circumstance occurred in Essex, which has subsequently been followed by such events that a regard for public safety, apart from all other considerations, compels me to give the utmost publicity to the facts, with the view to further investigation.

On the 17th of the month named, two little children, aged two and four years, whilst playing in their father's garden, plucked, and were supposed to have eaten, a few green grapes, but it was certain that in the course of the day they had eaten one apple and one or two pears. At about 4.30 P.M. they were both taken ill, cold and sick, and, at the suggestion of a neighbour, who thought their illness was premonitory of small-pox (their father having been in a house where that disease existed), a medical practitioner was sent for, but did not take any serious view of their condition. Medicine was prescribed, the dose being two teaspoonfuls every two hours. The first dose was given to the elder child about seven P.M., and soon after taking it "he appeared giddy, cold, and drowsy." These symptoms were followed by vomiting and violent purging. The younger child did not take his dose until about an hour after his brother. He was similarly affected. In two hours a second dose was given, and in each case the symptoms described were aggravated in an alarming degree. At about ten P.M. the condition of the children being evidently full of danger, their father again sought medical aid, but unfortunately without success, and on his return gave a third dose of the medicine, the elder swallowing all the dose, while the younger child spilt some. Soon after this third dose, in addition to vomiting and purging, convulsions, accompanied by great difficulty in breathing and foaming at the mouth supervened in each case, and continued together with insensibility up to their death, which took place on the 18th, the elder child dying at one P.M., and the younger at five P.M. It is worthy of attention, that according to the father's statement to me, the convulsions in both cases were peculiar; the bodies being, during a paroxysm, so stiff that when lifted they each seemed to be "one piece." No more of the mixture was given after the third dose, as another medical practitioner visiting the children some hours before death, other medicine was ordered.

In consequence of suspicions entertained by the father as to the nature of the medicine (which he had carefully preserved), an inquest was held, and a verdict of death from English cholera was recorded in each case.

Doubts still existing, the father consulted a physician in London, who, from effects produced by small doses of the medicine upon a little dog, and upon himself, advised that it should be handed over to me for analysis.

The result of a careful qualitative examination for poison was the discovery of veratria in the mixture, and, as a consequence, the Home Secretary, upon due representation, ordered an examination of the bodies, and the viscera, &c., were sent to Professor Taylor, of Guy's Hospital, for analysis.

The only communication that I had officially upon the subject was a request conveyed by the Superintendent of the Police of the District that I should hand over to him the remainder of the medicine for analysis by Professor Taylor, and this I did after retaining a quantity sufficient for my own investigation.

Professor Taylor reports that there was no trace of poison in the viscera of the children, and that the medicine proved to be a perfectly innocent mixture, "being nearly all common water, with a few grains of carbonate of ammonia, and a small quantity of wine of ipecacuanha." Not to occupy, unnecessarily, your valuable space, I will remark that the reactions obtained by me from the alkaloid separated

from the mixture, and which, in my judgment, proved it to be veratria, were—1st, a yellow, with cold concentrated sulphuric acid, changing on the application of heat, in a few seconds, to a beautiful carmine tint; 2nd, the production of a mauve colour by heating with concentrated hydrochloric acid; and 3rd, the production of a beautiful red, on treating it with acetic acid and protochloride of tin, and evaporating to dryness. These reactions cannot be obtained from a mixture such as is reported by Professor Taylor. They not only convinced me, but also my learned colleague, Dr. Letheby (whose opinion I append) that veratria was present in the mixture.

These discrepancies are serious even in their relation to science, but when it is further considered that they might be of enormous consequence in relation to a question of the cause of death, it is manifest that they should be cleared up with as much certainty and as little delay as possible, and this can easily be done if Professor Taylor has any of the mixture left as I have.—I am, sir, your obedient servant,

J. E. D. RODGERS, M.R.C.S., & L.S.A.,
Professor of Toxicology in the London Hospital
Medical College.

At Mr. Rodgers' request I state that I witnessed the reactions above described, and am of opinion that they indicate the presence of veratria.—(signed),

H. LETHEBY, M.B., F.L.S., &c., &c.

London Hospital Medical College,
November 27, 1866.

GARIBALDI'S CHARACTERISTICS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In page 509 of THE MEDICAL PRESS AND CIRCULAR you quote the different characteristics of Garibaldi; from the following fact you may perhaps add another:—In October I was at Bologna, and in the public market square I saw a man vending the skin and pieces of bone which was supposed to have been the parings of his bullet wound. The man boldly held out for their veritability, and as a proof of his statement showed an autograph letter from the General himself, appointing him salesman.—I am, &c.,

OSTENTATION.

28rd November.

Medical News.

THE remains of a complete skeleton of a huge mastodon, eighty-three feet below the surface, have been discovered at the village of Cohæ, near Troy, America.

A RABBI living at Jeville (Haute Marne) has recently died at the advanced age of 108 years. He retained the perfect use of his faculties to the last.

IN some parts of Cornwall osyters bred on one side of a river are so coppery as to be poisonous, while those on the opposite side are wholesome. By removal to other oyster beds the copper is in time eliminated, and the oysters are fit to eat, and even sought after by epicures.

THE use of Sir William Burnett's disinfecting fluid has been ordered to be discontinued on her Majesty's ships from the fact that several fatal cases of poisoning have occurred by its having been accidentally swallowed by seamen.

ARMY MEDICAL DEPARTMENT.—It is a noticeable fact in connection with the constant complaint of army assistant-surgeons respecting slowness of promotion, that less than three months since the seniors of these officers obtained their steps under twelve years' service, whereas now there are forty assistant-surgeons on the list who have completed twelve years' service. It would appear, from this fact, that the chance of promotion to a full surgeoncy (the great step) is daily becoming less and less. The evident reluctance of old surgeons-major of thirty years' service and upwards to take their half-pay retirement, is no doubt one of the causes of the plethora with regard to assistant-surgeons' promotion, those officers (surgeons-major) looking forward to their promotion to deputy-inspector-general's rank. However, as this list contains only twenty-seven officers, most of the expectants have but a week chance of having their hopes gratified.

IRISH REGISTRAR-GENERAL'S RETURN.—The return just issued records 18,751 deaths in Ireland in the third quarter of the present year, and assuming that all the deaths are registered, the annual rate of mortality is 13.4 to every 1000 persons living. The population of Ireland, estimated to the middle of 1866, is 5,582,625. Notwithstanding the outbreak of cholera in various parts of the country, the deaths during the past quarter were 103 less than the number registered during the corresponding quarter of last year. This may partly be attributable to a diminution in the zymotic diseases; but it is feared that registration in some parts of the country is imperfect. Deaths from scarlatina of a very malignant nature are reported in some districts; but where sanitary precautions had been adopted, the epidemic had disappeared or very much decreased. About thirty registrars reported cases of cholera, and it appears that in nearly every instance those who first suffered from the disease had recently been in localities where it was prevalent. It is stated that reapers and labourers on their arrival from England were attacked by cholera, and the disease was communicated by them to other inmates of the houses in which they resided. In Mallow 26 deaths from cholera took place, the greater number of them occurring in the vicinity of a well, the water of which was used for domestic purposes by the people residing in its neighbourhood. This water has since been analysed and found to contain a very large amount of organic matter derived from animal sources. At Arklow, in Rathdrum, 21 deaths have occurred from Asiatic cholera out of a total of 58 deaths for the quarter. The town is in a very filthy condition, the drainage is extremely deficient, and the supply of water is procured from shallow wells and pumps, containing matter deleterious to health. The present outbreak of cholera in this neighbourhood is stated to have been most virulent within a circle, the centre of which is one of these shallow wells. Another source of disease in this district is said by the registrar to emanate from the practice of the poor people allowing pigs to sleep in their cabins during the night, while they are left to prowl during the daytime among the cesspools of the town. At Carrick-on-Suir, and also at Milltown Malbay, the registrars testify to the advantages derived from the recent adoption of sanitary improvements. The births registered in Ireland in the quarter were 33,580, or 24 to every 1000 persons living; the births in the corresponding quarter of last year were 34,158. The marriages (6,045 in number) are for the second quarter of the present year, and show an increase of 384 over the numbers in the corresponding period of 1865; to every 1000 of the population 8.33 persons married; 3941 marriages were between Roman Catholics; the remaining 2104 were between Protestants. According to the emigration returns the number of emigrants who left the ports of Ireland during the past quarter was 19,640, being 8021 less than the number who emigrated during the corresponding period of 1865. The mean temperature of the air in Ireland was 56.9 deg., or 3.9 deg. lower than in the September quarter of last year. Rain or snow fell on 56 days, and the rainfall measured 6.656 inches. The average prices of potatoes for the quarter were 3s. 8d. to 5s. 2d. per cwt., being much higher than the average prices for the corresponding quarter of last year—viz., 2s. 8d. to 4s. per cwt.

PATHOLOGICAL SOCIETY OF DUBLIN.—The first meeting of the twenty-eighth annual session of the above Society was held on Saturday, the 24th ult., in the anatomical theatre of Trinity College, Dr. McDowel, President, in the chair. At the conclusion of the ordinary business of the day, the subject of the Society's gold medal for 1866-7 was announced to be "The Diagnosis and Pathology of Diseases of the Shoulder-joint." The following officers were then elected for the Medico-Chirurgical year now commencing:—President—Robert W. Smith; Vice-Presidents—Joseph M. O'Ferrall, Awly Banon, John Denham, George Kidd, Robert Adams, and Sir Dominic J. Corrigan, Bart.; Council—John Banks, Thomas Beatty, Maurice Colles, James Duncan, Christopher Fleming, Samuel Gordon, Edward Hamilton, James T. Hughes, Benjamin G. McDowel, Alfred H. McClintock, George H. Porter, and Joliffe Tufnell; Honorary Secretary—William Stokes; Secretary—Robert Law; Secretary for Foreign Correspondence—Robert D. Lyons.; Treasurer—Robert W. Smith.

Mr. Edmund Sharpe has presented to the British Museum a statue of the son of Rameses the Second, about

four feet high. He bears a standard on each side; it is of most beautiful workmanship, on hard polished breccia. It is placed near the head of Memnon, in the Egyptian Gallery. It is in a very good state of preservation, and is a beautiful specimen of Egyptian art. It is curious as a lithological specimen, the breccia being formed of the consolidated sand of the desert, inclosing jasper, chert, and other siliceous pebbles.

The following pensions on the Civil List have been granted:—Dr. Arthur Hassall, £100 a year, on account of his eminence as a scientific chemist, and his services in connection with the inquiry into the adulteration of food; Mrs. Carpenter, £100 a year, on account of the services of her husband, the late Mr. Carpenter, as Keeper of the Prints and Drawings in the British Museum, and of her own merit as a portrait-painter; Mrs. Sykes, £75 a year, on account of the services of her husband, the late Mr. Godfrey Sykes, to the industrial arts of the country, and to the Museum at South Kensington; Mrs. Coulton, £75 a year, on account of the literary merit of her husband, the late Mr. David Coulton; Dr. Patrick White, £75 a year, in consideration of his services as an author, public lecturer, and illustrator of the minstrelsy and bardic literature and music of ancient and modern Ireland; Henry John Doogood, Esq., £40 a year, for many years engaged in literary pursuits, and in connection with the public press as a Parliamentary reporter, and now blind and paralyzed; George Thomason, Esq., £40 a year, on account of his services in connection with the periodical literature of the day, being now afflicted with blindness; Robert Young, Esq., £40 a year, in recognition of his services as an historical and agricultural poet in Ireland; Miss Mary Craik and Miss Georgiana Craik, £30 a year each, in consideration of the services of their father, the late Dr. Craik, as Professor of History and English Literature in the Queen's College, Belfast.

THE extensive and valuable collection of microscopic sea-weeds, technically known as Diatomaceae, belonging to the late Dr. Greville, has been recently acquired by the Botanical Department of the British Museum. They contain all the type-specimens so exquisitely figured by him in the "Transactions of the Microscopical Society," and in other journals, as well as of the more obscure species described and figured by the late Prof. Gregory. It is fortunate for the numerous students of these minute organisms that they have become the property of this national institution, and been added to the typical collection of the late Prof. W. Smith. This large series of authentic specimens, now the property of the public, will at all times be accessible for the identification of obscure species, and for the clearing away of doubts.

THE MEDICAL ACT.—The 29th section of the above Act, recites that, "If any registered medical practitioner shall be convicted in England or Ireland of any felony or misdemeanour, or in Scotland of any crime or offence, or shall after due inquiry be judged by the General Council to have been guilty of infamous conduct in any professional respect, the General Council may, if they see fit, direct the registrar to erase the name of such medical practitioner from the register." Acting on this power the General Council of Medical Education and Registration of the United Kingdom has just published the following list of delinquents, with the causes which gave rise to the punishments now inflicted on these persons—viz., John Edward Protheroe, name erased in consequence of the entry of it having been fraudulently obtained; Richard Organ, for infamous conduct in a professional respect; John Burton, the entry of his name having been fraudulently or incorrectly made; John Broatch, in consequence of false declaration; John Kearney, for infamous conduct in a professional respect; Daniel de la Cherois Gourley, in consequence of his having been convicted of a misdemeanour; David Griffiths Jones, in consequence of his having been convicted of a misdemeanour; Evan Thomas, in consequence of his having been convicted of perjury; Robert Wrixon, having been convicted of forgery; Samuel La Mert, for infamous conduct in a professional respect; Robert Jacob Jordan, his qualification of M.R.C.S. England erased in consequence of his name having been removed from the list of members of that College, and his qualification as licentiate of the R.C.P. Edinburgh, for the same reason; John Carter Barrett, having been convicted

of forgery; William John Cumming, having been convicted of felony; Robert Abercrombie, his qualification of M.R.C.S. England erased in consequence of his having been removed from the list of members of that College; Thompson Whalley, having been convicted of a misdemeanour; and John Permewan, having been convicted of felony.

Notices to Correspondents.

F.R.C.S.—Tinnitus aurium attends upon most diseases of the ear. Dr. Yearsley's theory is, that it arises from pressure, and he adduces the following facts in confirmation of it:—1st. The pressure of the finger on the outer passage produces it. 2nd. The pressure of indurated wax on the membrane tympani produces it. 3rd. The pressure of inflamed structures within the cavity of the tympanum produces it. 4th. The pressure from bands of adhesion, one of the consequences of inflammation, produces it. 5th. The only cases which come before the aurist, unattended by tinnitus are, in nine cases out of ten, when there is loss of the membrana tympani. This lesion relieves the pressure, and *there is no tinnitus!* Dr. Yearsley further asks:—Noises in the head generally, and extending to the ears, are they not also explicable on the same theory—pressure?

Mr. Richardson's letter has been received, and will appear in our next number.

Communications received from Dr. Lane, Dr. Smyth, Mr. Forsyth, Dr. Hannan, Dr. Clark, Dr. Oppert, Mr. Northcote, Dr. Kidd, &c.

Appointments.

EASTLAKE, HENRY E., F.K.Q.C.P. &c., has been elected Consulting Physician-Accoucheur to the Western Dispensary, Westminster vice Dr. Mark Tanner, resigned.

FOX, CHARLES JAMES, Esq., has been elected Assistant Dental Surgeon to the Dental Hospital of London, vice J. Walker, Esq.

DRYSDALE, C. R., M.D., has been appointed Assistant-Physician to the Metropolitan Free Hospital, Devonshire-square, E.C.

ELLISON, J., M.D., has been appointed Joint-Surgeon and Apothecary to her Majesty's Household, Windsor.

FAIRBANK, J., M.B., has been appointed Joint-Surgeon and Apothecary to her Majesty's Household, Windsor.

LONGSTAFF, CHARLES, M.D., has been appointed Assistant-Surgeon to the Royal South Hants Infirmary.

RANDALL, J. G., M.R.C.S.E., has been appointed House-Surgeon to the Female Lock Hospital, Harrow-road.

RICHARDS, J. P., M.R.C.S.E., has been appointed Assistant Medical Officer to the Devon County Asylum.

SCOTT, GEORGE, M.D., has been appointed Assistant-Physician to the Royal South Hants Infirmary.

SILVER, ALEXANDER, M.A., M.D., late Assistant Professor of Materia Medica and of Medical Jurisprudence, University, Aberdeen, has been appointed Lecturer on Botany at the Charing-cross Hospital School of Medicine.

STEWART, HUGH GRAINGER, M.D., has been appointed Lecturer of Medical Psychology in the Newcastle-on-Tyne College of Medicine.

WANE, W., M.R.C.S.E., has been appointed House-Surgeon to the Stockport Infirmary.

PROPERTY, JOHN, Esq., has been elected Vice-President of the Society for Relief of Widows and Orphans of Medical Men, at the half-yearly general meeting on October 31st, vice D. Henry Walne, Esq. deceased.

"SALUS POPULI SUPREMA LEX."

INTRODUCTORY LECTURE,
DELIVERED IN THE
MEATH HOSPITAL.

By WILLIAM STOKES, Jun., M.D., Ch.M., L.R.C.S.,
SURGEON TO THE HOSPITAL.

THE duty of opening the Medical Session in this hospital have undertaken with mingled feelings of satisfaction, trust, and confidence. Of satisfaction, inasmuch as it affords me occasion to offer to my colleagues, especially to the gentlemen forming the class of this hospital, and to many friends who have honoured me by their presence here to-day, my heartfelt thanks for all the thoughtful kindness and sympathy they evinced towards me during my recent long and tedious illness. To be silent will be, perhaps, the best expression for my feelings on this subject, and probably the one best understood by you. I cannot but be distrustful, on looking at the exalted nature of my task, and the imperfect nature of my qualifications for it, but also confident, from the lively recollection I have of the kind indulgence and liberality I experienced, while my health was spared, in clinical teaching and surgical investigation, not only on the part of my respected colleagues, but also of the gentlemen forming the class of this hospital.

The custom of delivering introductory lectures, which exists in the great majority of British hospitals where clinical instruction is given (and medical schools) is one, the practical utility of which has been questioned by many, being looked upon as an ornamental appendage—in fact, a sort of rhetorical royal salute to indicate the commencement of the session, which may be very well dispensed with. I am not, however, inclined altogether to endorse this opinion; for, though I do not think any very great advantage in the way of increasing knowledge is ever obtained by the student from such discourses, yet it appears to me to be not altogether unproductive of advantage, for the junior student especially, who is beginning, we may say, that which is to be the labour of his life, to have some of the objects of his study indicated to him; and to the more advanced student to have not only these, but also some of the results recently attained, actual tendencies, and prospects of surgery or medicine, call it what you will, briefly discussed with some degree of clearness and truth. Should I be at all successful in doing this, my highest object will be attained. It will, doubtless, be expected of me by many of you, gentlemen, that I should follow the course usually and very properly adopted in inaugural addresses of this kind, of giving advice on various matters connected with your medical education. Advice, however, I believe, is seldom much valued, no matter from whom it comes, but certainly never thought anything of, unless it comes from one whose long standing, extensive experience, and, let me add, professional success, are not matters of question. The advice of persons so fortunately circumstanced will, doubtless, carry a certain amount of weight with it, and they are, therefore, quite right to give it. It is, at all events, ever a matter of interest to hear indirectly indicated the methods they have individually adopted for advancing as well their own interests as those of our profession and our science. From me, however, you will, I trust, accept the observations I am about to make to you, as coming altogether from one of yourselves, having made but little, very little, further advance in the arduous undertaking that we are at present engaged in here. I shall assume, therefore, that having consulted with your friends and

advisers, you are aware how essential a knowledge of anatomy is, that it is, in fact, the alphabet of surgery; and also that the details of your studies in this and the other sister sciences of medicine, physiology, chemistry, materia medica, &c., have been fully explained to you by your respective teachers.

Gentlemen, I have stated that I shall avoid giving you advice, but, at the risk of being considered contradictory, I must indicate one means for acquiring a knowledge of your profession to which I am satisfied all others, whether they be systematic courses of lectures, private teaching, or reading, should be secondary, entirely subsidiary. I mean that method of studying disease which has been *par excellence* the mode of investigation adopted by the great medical and surgical teachers in the Dublin school, and which they have consequently raised to its present exalted position amongst the European schools of medicine. I believe the method to be adopted by the student in his first year for acquiring a knowledge of the veriest elements of surgery, and that for the original investigator, the pioneer, should be the same—namely, clinical study. While you are here, therefore, diligent hospital attendance should be your first as well as your last duty; and by this I mean far more than mere constant attendance at hospital. The proportion of students in every hospital class, who are content to attend with great regularity, it may be, but who do nothing but walk round the wards, and afterwards criticise generally with more severity than justice what they have seen and heard, is very considerable. The advice I wish to give you—the only advice—is to investigate and make records of the cases for yourselves. Your first attempts will necessarily be crude and imperfect; but as the old saying is, "a beginning is the half of all," and if the records were in themselves of little value, still by doing so, no matter in how imperfect a manner, it gives the habit of observing for oneself, and in this way it is one of the greatest importance. The late Sir Benjamin Brodie's observations on the importance of case-taking, while a student, are so well known that I shall refrain from quoting them; but to the junior student, who probably has not heard them, I may mention, in passing, that even in the later years of the brilliant career of that distinguished surgeon he was in the habit of occasionally referring to cases which he had taken even in the earlier period of his pupilage, and from which he derived no small assistance in his extensive practice. This is, I am convinced, the true method of studying medicine, as well for the student as for the teacher. It is not, as is held in some schools, by paying exclusive attention, for example, to organic chemistry, to microscopical investigation, or to any one other of the kindred sciences of medicine that advancement is attained; but our ambition should be to be in such a position as to be able to apply these, but not rely solely on them, as some would have us do. The knowledge of this or that fact is not by any means the only thing which is needed for successfully combating disease. It is very well for the sailor to know the freight and ballast of his ship, but when the storm arises and rocks are ahead, it is far more important for him to know thoroughly how to pilot her, for without that knowledge all may be lost. You cannot either commence this method of learning disease at too early a stage of your career as students, the period for which in this country is so short. In Sweden, for example, a pupil cannot obtain his diploma until he has been for ten years a student, two of which he must have spent as an intern of a general hospital. In Germany he must be five years, in Austria also five, and in France six years, a student. In British schools of medicine all qualifications can be obtained at the end of the third year, and if he extend the period of his pupilage beyond four years he runs the risk of being stigmatised by his friendly contemporaries as being a "chronic man." Do not, therefore, let yourselves be influenced by the advice of those who would recommend you to abstain from hospital attendance during your first year. Indeed, I can hardly conceive anything more

likely to be permanently injurious to you than the adoption of such a recommendation. Advice of this sort appears to me to be as absurd as it would be to recommend a boy not to go into the water until he had first learned how to swim. Already custom has rendered in this country the term of pupilage far too limited, and every day spent away from hospital is a day lost. The study of nature is a thing one cannot have too much of. It is as essential to us to commence it from the very start, as it is to those who make the fine arts their pursuit, whether they be painters or sculptors. In addition to many other reasons I might give you why you should begin clinical study at an early period of your studentship, is this, which you may often, probably, have heard before—viz., that the recollection of what one sees or hears at commencing the investigation of a new study clings to him with a peculiar tenacity. This is well expressed in the words of an eloquent writer, who observes that "all knowledge which alters our lives penetrates us more when it comes in the early morning"—

"Truth can never be confirmed enough,
Though doubts did ever sleep."

The future historian of the condition of and progress made in medicine during the present epoch will have to admit that the two things indicated so well by Mr. Grove in his remarkable address to the British Association, as characteristic of modern investigation in other branches of human knowledge, were least of all wanting in the present investigation of that science to which we have devoted ourselves—namely, a warfare against empiricism and dogmatism, and a hostility to all that is antagonistic to the intellect, to all that observation cannot testify and reason endorse. This is seen in many other branches of human knowledge as well as in medicine. We have, of late, seen the attempt made not only in religion, but also in politics, in history, and in art—the desire to supplant what is founded on dogma and empiricism for that which has for its base what is seen, and what reason determines; and all traditional and theoretical opinions which do not bear the keenest investigation and that cannot be verified by observation immediately fall to the level they deserve. "All kinds of things," says Carlyle, "are coming to be subjected to fire, as it were: hotter and hotter blows the element round everything. Curious to see how in Oxford and other places that used to seem as lying at anchor in the stream of time, regardless of all changes, they are getting into the highest humour of mutation and all sorts of new ideas are afloat. It is evident that whatever is not inconsumable, made of *asbestos*, will have to be burnt in this world. Nothing other will stand the heat it is getting exposed to."

The result of this feeling among the workers of our science has been the introduction of the so-called physical diagnosis by which is meant the application of various physical sciences, such as chemistry, acoustics, and optics, to establish with perfect and unquestioned accuracy the nature of various pathologico-physical alterations. To discuss with any degree of completeness all that has recently been done by their means, in this direction, would be, on the present occasion, impossible. Time would not admit of the attempt being made. But I may allude to some of the advantages that have been gained for medicine by the application of optical science. And I mention these in preference to others, as they are more likely to engage at present, and be more immediately available to the medical practitioner in the fullest sense, than the results which have been obtained by the application of the other sciences to which I have alluded. In physical acoustic diagnosis, for example, it cannot be said that there is any single pathognomic sign of any single disease. The diagnosis, if we limit ourselves to its physical side, depends not merely on the acoustic character of the signs, but on their combination and on their mode of succession; and with all these aids it is necessary, in the great majority of cases, to combine the consideration of the vital pheno-

mena, that is to say, the constitutional symptoms, with those of physical signs. But if we take the ophthalmoscope, we only require the exercise of a single mode of observation, so that the conclusion is arrived at more directly and is more accurately determined. He would be rash indeed, who would say that we have arrived at the furthest limit of that knowledge we have so recently obtained by means of this instrument. I say recently obtained advisedly, for it is not more than thirteen or fourteen years since Helmholtz, seeking to determine two questions—one, why it is that under certain conditions we can observe a luminosity in the eyes of some animals, and the other, why it is that the pupil appears black—was led to devise an instrument by which he was for the first time enabled to view the fundus of the eye. From Helmholtz' first publication on the subject of his discovery may be seen that his expectations as to the advance of our knowledge that would be made by it have been far exceeded. He observed:—"I do not doubt, judging from what can be seen of the healthy retina, that it will be possible to discover all its diseased conditions, as far as these, if seated in other transparent parts, such as the cornea would admit of diagnosis by the sense of sight. Distension or varicosity of the retinal vessels will be easily perceptible. Exudations in the retinal substance, or between the retina and choroid, will be seen precisely the same as in the cornea by their brightness upon dark ground.

Fibrinous exudations, usually much less transparent than the ocular media, will, when lying upon the fundus, considerably increase its reflection. I believe, also, that turbidity of the vitreous body will be determined with great increased ease and certainty. . . . In brief, I do not consider it an overstrained expectation that all the morbid changes in the retina, or the vitreous body, that have been found in the dead subject will admit of recognition in the living eye—an expectation that appears to promise the greatest progress in the hitherto incomplete pathology of this organ." From these observations may be seen that Helmholtz did not anticipate the extension of our knowledge of pathological change by means of the ophthalmoscope beyond mere local ocular diseases. But how much more have we learned? The connection, for example, between retinal diseases and embolism, also between it and Bright's disease, lucenia and diabetes; or, in other words, the connection which is occasionally observed between retinal disease and various constitutional affections. The application of it, also, to the diagnosis of many diseases of the nervous system presents, apparently, a wide field for investigation. No one familiar with the researches of Bouchut, especially on the symptomatic form of paralysis of the sixth pair of nerves, "abducens paresis," as it is termed, and in which he dealt with the difference between this and the idiopathic form of the disease, one the etiological conditions of which have for so long been veiled in obscurity, can help being convinced of this. Thus enabled by the ophthalmoscope to detect not only deep-seated local ocular disease, but also occasionally the expression in the retina of some forms of cardiac and cerebral diseases, a knowledge of the use of this instrument becomes of paramount importance not to the specialist alone, but also to the medical and surgical practitioners in the widest sense.

Following closely on the discovery of the ophthalmoscope by Helmholtz came the introduction into medical and surgical practice of the laryngoscope. Nothing can be of greater value than the results, both positive and negative, that have been obtained by this means of studying laryngeal disease. Its utility, for example, in determining accurately various forms of ulcerations, neoplasms, and many other organic changes; and also it is of vast importance in its application to various forms of nervous aphonia, to the early stages of phthisis laryngea, and to that form of aphonia depending on aortic aneurism. And the great practical value which is obtained is, that it has led to a more rational system of therapeutics, superseding the

uncertain courses of treatment dictated solely by empiricism, which were previously prescribed.

The last application of optical mechanism which has been applied to the investigation of disease by direct observation has led to the introduction into surgical practice of the endoscope. The priority of its invention is claimed by more than one. But for making the instrument of real value to the practitioner the profession is indebted to Dr. Cruise, of this city, who has laboured long and successfully at perfecting this important aid to diagnosis. It has already enabled us to view, with the most perfect distinctness, various pathological conditions of the rectum, uterus, urethra, and bladder; and for the examination of the nasal fossæ it appears to me to possess many advantages over the rhinoscope. It promises, also, to have a much wider application.

Let us not, however, look upon those modern scientific victories as in any way affording us a "royal road" to diagnosis, but in striving to estimate their proper value, and the uses to which they may be turned, regard them only as aids or helps, to which no small amount of labour will be required to attain dexterity in their use. It has been curious to note how differently the introduction of these instruments into medical and surgical practice has been received by the profession in various places. Some, having little or no appreciation of the spirit of progress of the age, and whose sympathies are only with what preceded them, unhesitatingly condemned all such innovations as being untrustworthy, and, therefore, of little use. And so it has always been. It was so when the stethoscope was introduced into practice; but in a short time in what different estimation was it held! And recently how often have men sneered at the ophthalmoscope and laryngoscope, and termed them "toys!" Such men, however, no matter how learned they may be, or how much of the so-called "practical" experience they may boast of being possessed of, never move the spirit of their age. The man who would urge you to stand still, with closed eyes, content with the present and what you have of knowledge should ever be shunned. For nothing is more absolutely fatal, especially in the medical character, than indifference and scepticism. On the other hand, there are many who delight in making every improvement, innovation, or discovery the theme for hostile comparison with what was formerly in use—men who never can travel in an express train without a sneer at the old stage coach in which our fathers travelled, or handle a needle gun without making some invidious observation about the old musket, the weapon with which Napoleon and Wellington armed their troops. However, it is not the philosopher, but the fool, that is indicated by such a flippant consciousness of superiority. He would be rash who would say that all the dreams of the alchemist, so often derided, and termed ignorant impostors, were utopian. The great existing chemists think far otherwise, and acknowledge that many of the problems propounded by the alchemists are still unsettled, and are slow in declaring that many of those dreams which are most startling to us are impossible to realise. Indeed, in dealing with matters connected with either natural or scientific progress, the word "impossible" might well be erased. For history is, after all, nothing but a series of so-called impossibilities, many of them occurring contrary to all rational forecast. The greatest intellects, whether political or scientific, are continually taken by surprise at the occurrence of unforeseen events. Many examples might be adduced in illustration of this, which tend to show forcibly how slow we should be to declare results, by us unforeseen, as either impossible of attainment, or, if attained, useless for practical purposes. An eminent mathematician proved, at all events to his own satisfaction, if not to that of his hearers, at one of the meetings of the British Association held at Bristol some twenty-eight or thirty years ago, that no steam-vessel could carry a sufficient amount of fuel to supply the engine fires for the time necessary to cross the Atlantic; and the great

Napoleon, I have heard, died disbelieving in the practicability of propelling any vessel against wind and tide. And to come to a much more recent date: looking at the present year, we have been spectators of two events that few, if any, could have foretold at its commencement, and which will ever take a foremost rank among the annals of the world. Both widely different, and brought about by means the most dissimilar, yet both tending to the same great and noble end—national unity. The one accomplished amid all the ghastly horrors and heartrending scenes of colossal war—the other a peaceful triumph, conferring a far wider and far greater boon on mankind, and accomplished, not by the ruthless sword, but by British enterprise and British skill.

In Germany, we have seen all but realised that which has been so long the happy day-dream of her truest sons—her unity; and nearer home we have witnessed with feelings of genuine pride and admiration a greater triumph than that of Sadowa—the union of the old and new worlds by a magic thread, and another powerful and enduring link added to the great chain of causes, which in silence, almost without perception, is bridging over the wide chasms which separate nation from nation, and the countless races of man. It would be hard, indeed impossible, to realise its future influence on human civilisation. "Now," in Mr. Bowman's eloquent words, "man's thoughts, cyphered with unerring truth by silent-speaking symbols, in the last degree refined, and borne onwards by tender tremors of the metal, fainter yet far fleetier than Æolian whisperings, are traversing every moment the awful solitudes of Atlantic depths, under miles of ambient water, where no sound, hardly light itself, can ever penetrate; all heedless of the fogs, and icebergs, and mimic storms of the surface, 15,000 feet above. And soon the very globe itself will be woven over with a time-annihilating network; a blessed harbinger as well as an eventual promoter of good-will and peace, of peace and good-will to all mankind." Gentlemen, we have seen and welcomed the tendency of late years to apply to the investigation of disease those physical sciences that I have before mentioned. And we have seen also what brilliant and unexpected results have been attained. But far more than this has been done. As all rational therapeutics can only be a reflex of pathological theories, other means in addition to chemistry in its widest sense, the microscope, and all other applications of optical mechanism, have been had recourse to in seeking to establish the one, and legitimising, consequently, the other. The mere observation of disease has not in my time been fruitful in suggesting to us reliable therapeutic methods; these have been indicated rather by prevailing physiological ideas. One remarkable exception to this probably occurs to many of you, and that is the operation of iridectomy for glaucoma, which procedure, out of Germany, is still in an unhappy *sub judice* condition. Other exceptions to this may occur to some of my hearers, but all have still to bear the test of time, and will, in all probability, be abandoned unless found in harmony with established facts. The method of investigation which I allude to, and which has already done and promises to effect so much towards the improvement of surgical therapeutics, is experimental physiology. Against this the once loud but absurdly sentimental outcry is now, fortunately, become so feeble as hardly to be heard. In France the importance of explaining human pathology by experimental physiology has been fully recognised by the enlightened Government of that country, and, accordingly, a chair of Comparative Pathology has been established in the Paris Faculty of Medicine. It would be impossible for us on the present occasion to attempt discussing all that has been gained for us in this direction by physiologists. I may mention, however, what appears to me to be one of the most important results of this method of investigation for operative surgery; one which has in many places entirely altered the mode of procedure in what may be ranked among the most formidable of surgical operations—namely, the resection of

the larger joints. This change has taken place in consequence of the attention of surgeons having been directed, by Professor Syme first, and afterwards by M. Ollier, to the remarkable osteogenetic properties of periosteum, which were at all events but imperfectly understood previous to the important researches of these and other eminent surgeons. Now, not only in resections is the importance of carefully preserving this membrane recognised, but other operations have been signally modified. The transplantation of the membrane, for example, in the so-called Indian Rhino-plastic has many advocates, and in the Urano-plastic operation for the repair of defects in the hard palate, resulting either from disease or congenital malformation, this is now a fully recognised step of the procedure.

The priority of this modification in this operation is claimed by the Berlin school, but I do not think altogether with justice, for it cannot be denied that for many years anterior to its publication in Berlin it was in America performed in this manner by Mr. Warren, and in this hospital the practice of my colleague, Mr. Collis. In the recent wars in America, in Schleswig-Holstein, and Bohemia, the importance of careful periosteal preservation has been fully recognised by military surgeons. Amongst others, Dr. Moon, of Philadelphia, relates a case of absorbing interest of a man whom he treated for a gunshot wound in the right leg, which he received at the battle of Petersburg in July, 1864. Some of the particulars of the case are related as follows:—"A Minié ball entered the upper third of the outside of the right leg, passing down obliquely through the spine of the tibia at its middle third, carrying away a small portion of the bone, and emerging at the inner side of the leg. The injury to the bone, though apparently slight, proved to be one of those contusions which destroy the vitality of the tissues to a considerable extent, and eventuate in a large amount of morosis. Sloughing of the soft parts first in the track of the wound, and then of the bones, supervened. The slough of the bone also extended until two-thirds of the tibia became involved in its entire circumference. Abscesses formed constantly, which were required to be opened. Active inflammation subsiding, it was decided to remove the sequestrum, which proved to be eight inches and a half in length, from the epiphysis of the ankle-joint. The periosteum being in a measure loose, and quite easily detached, the posterior portion of it was left in the entire extent of the shaft. An incision along the spine of the tibia, exposing nine or ten inches of the bone was made, when the sequestrum was readily removed by means of bone forceps. The case progressed rapidly and favourably, new bone forming the whole length of the periosteum left in the wound." On May 10, 1865, he wrote—"I am at work at my trade, coach-building, and have complete use of my injured leg, running up and down stairs as well as any of the workmen. The wound has entirely healed, and new bone formed throughout." In another case five inches and a half of the tibia were removed, the periosteum being left, and resulted in a like cure. A still more remarkable case occurred during the recent Schleswig-Holstein campaign in 1864, in which the Prussian Surgeon-General, Professor Langenbeck, performed a sub-periosteal resection of a large portion of the diaphysis of both tibia and fibula, and which was brought to a successful termination with complete re-formation of bone. In this war, also, five cases of sub-periosteal resections of the ankle-joint were performed by him, four of which recovered. In general, however, the resections were not so successful as they were during the first Schleswig-Holstein war in 1848, and this, Professor Langenbeck informed me, he attributed to the recent improvements in gunnery, which, at all events, as surgeons we must deplore. Owing to this, the injuries met with on the field of battle now, and requiring resection, are generally much more formidable than they used to be. For the bone, when struck, is to a great extent actually pulverised, and the minute

particles of bone, being driven in all directions through the surrounding muscular and other soft tissues, produce in this way a condition of parts most unfavourable for resection. This may possibly account for the ill success of the American military surgeons in their performance of the operation at the knee joint. Not one of the numerous cases reported in Circular No. 6 (a most admirable account published last spring by the American Government of the surgical experiences acquired during the war) terminated successfully. This must, doubtless, carry some weight in estimating the merits of this procedure, which has so long been a subject of surgical dispute in the Dublin school. However, we should be very slow in forming any decided opinion on its merits in civil practice from experience of this sort alone. For, in addition to what I have mentioned, the exciting collateral circumstances which necessarily exist must militate strongly against successful results being obtained in surgical operations of such magnitude.

M. Ollier, of Lyons, as I mentioned previously, has directed especial attention to the importance of periosteal preservation and transplantation in many operations. In three cases he has removed large portions of the diaphyses of the long bones with favourable results. In his other cases an epiphysis of the bone had to be removed. One of these I had an opportunity of seeing, in which the upper half of the humerus was removed, with complete restoration of bone. From his experiments, therefore, and clinical experiences, as well as from those of some others who are deeply interested in this subject, and from the cases of Dr. Moon and Professor Langenbeck, the following propositions may be stated:—

I. That in sub-periosteal resections the reproduction of bone is more complete and effected with greater rapidity than after total removal of both bone and periosteum.

II. That the osseous reproductive properties of the membrane vary according as it is taken from the long or the short bones, being greater in the former than in the latter (Ollier).

III. That the normal form of the joint is better preserved when this precaution of leaving the periosteal covering is taken.

IV. That the sub-periosteal resections involve less danger than when conducted on the old principle. This proposition is grounded on the result of experiments on the lower animals, the number of unfavourable results which followed when the membrane was removed being much greater than when it was left.

V. That the difficulties attending the separation of the membrane in the dead subject are not to deter us from attempting the operation on the living, inasmuch as the membrane is less adherent in the latter, and also in the diseased than on the healthy bone.

VI. That resections performed in this manner are more conservative, inasmuch as a re-formation of the part removed is effected, and, being attended with less risk to life than the ordinary resections, a greater quantity of bone can be removed, and in this way in a number of cases the necessity for amputation is diminished. The cases I have alluded to—of Dr. Moon in America, and Professor Langenbeck—are illustrative of the truth of this.

VII. That the chances of much shortening of the limb are diminished by this method, as shown by the results of the ankle joint resections during the late Schleswig-Holstein war.

VIII. That in addition to these the modified Rhino and Urano-plastic operations demonstrate that the happiest results have been obtained by this application of experimental physiology to practical operative surgery.

Gentlemen, were I to attempt to discuss all the improvements and innovations that have been recently made in operative surgery here and elsewhere, I should, I fear, exhaust your patience. Many of these procedures are entirely novel, others revivals too hastily abandoned by the immediate followers of their projectors; thus giving

us a useful lesson, in showing us that if we are to be slow to accept we should be also slow to reject; for the great majority of such proposals come to us bearing credentials, signed by names that will ever be revered and cherished so long as there are men to be found to do honour to the true worker and brave pioneer of our thrice noble science.

We may look proudly on the past history and present position of the School of Medicine in Ireland, and I congratulate you on belonging to it; for, as it has fallen to my lot to acquire considerable personal experience of many foreign schools, I can assert, without fear of contradiction, that there are none in which the advantages possessed by the student are greater, and few, very few, in which they are so great. The four corner stones of our National School of Medicine have been perseverance, courage, hope, and work. The foundation has been laid on a spirit of true philosophical eclecticism, the good being taken from every source, and tested by its application to the healing art. This spirit has been more developed in Dublin than in any of the other British schools, or, indeed, in any with which I, at least, have had opportunity of acquiring experience. It was this spirit that animated the founders and supporters of our school, a long and honourable list, and not a few of whom made this hospital the arena for their labours. Of these, two, I may say, recently have rested from their work—the late Professor Porter, and my immediate predecessor, Mr. Smyly, two men, whose memory, whether they be regarded as great surgeons, honourable gentlemen, or true friends, will ever be respected and revered. All such supporters as these have been true patriots, and have recognised the great truth that *prestige* among the nations is now not so much a question of wealth and armaments, as of education in its widest sense; for in raising the character of their school they raised their country. Would that every class and every interest in this country had followed their example! Had they done so, we should not have witnessed the political strifes and utterly disastrous religious dissensions that have now, as they have done for generation upon generation, destroyed the prosperity and cruelly wrecked the peace of our native land.

Many of these true workers are gone, some but recently, but many still live, and may they long be spared to cheer us by their presence and encourage us by their example. No matter at how great an interval, let it be our ambition to follow in their wake. Men of much creative genius are, as they have ever been, rare in their generation. But those without this may not the less be "true sons of their century," for it is the men of order, the men who work with method, earnestness, and truth, that do the great mass of the world's work. If they have not strength to carry a votive tablet to the temple of Truth, they can, at all events, assist in fixing and cementing it; and fortunate it is that such is the arrangement made by the One Perfect Workman, for it shows us the importance, nay, necessity, of mutual help; for this must exist so long as men's qualities, mental powers, and tastes are so diverse. But, nevertheless, we are all, so to say, of the same guild; all have the same duty; and all can "allow," as Lord Bacon says, "the spials and intelligencers of Nature to bring in their bills." Nature, an illimitable ocean, lies outstretched before us, often casting a fair pearl at our feet, which we prize, not merely because it may increase the happiness and welfare of mankind, but also because of its own intrinsic beauty. When we see the vast benefits that have accrued to mankind by the possession of a few of her gifts, what may we not hope for in the future, when her richest jewels are obtained, now lying where, perhaps, as yet no light or sound has ever penetrated:—

The future hides in it
Gladness and sorrow;
We press still thorow,
Naught that abides in it
Daunting us—onward.

And solemn before us
Veiled the dark portal—

Goal of all mortal;
Stars silent, rest o'er us,
Graves under us silent.

While earnest thou gazest
Comes boding of terror,
Comes phantasm, and error
Perplexes the bravest
With doubt and misgiving.

But heard are the voices,
Heard are the sages—
The world's and the age's—
"Choose well—your choice is
Brief, and yet endless.

"Here eyes do regard you
In Eternity's stillness—
Here is all fulness,
Ye brave, to reward you,
Work, and despair not."

REPORT OF A
CASE OF JAUNDICE; CO-EXISTENCE OF
THE HÆMORRHAGIC DIATHESIS;
UMBILICAL HÆMORRHAGE;
FATAL RESULT.

By G. de GORREQUEB GRIFFITH,

LATE RESIDENT SURGEON AT THE HOME FOR DISEASES OF WOMEN AND CHILDREN; PHYSICIAN TO THE FAMILIES OF THE OFFICERS OF MILLBANK PRISON; PHYSICIAN TO THE HOSPITAL FOR DISEASES PECULIAR TO WOMEN AND CHILDREN; PHYSICIAN-ACCOCHEUR TO ST. SAVIOUR'S MATERNITY.

As the following is a rare case, and replete with very much interest, and, moreover, as many such have not been put on record, I take the opportunity of publishing it:—

Mrs. G. S. came to me some time since when she was suffering from the symptoms of extreme anæmia. She was then a few months advanced in pregnancy, and applied to me because she feared for herself her approaching confinement, having suffered very greatly on the occasion of her last, when she gave birth to her first child.

She remained under treatment till the symptoms of anæmia had wholly disappeared. There was, however, but little improvement in her condition as regarded the development of either muscular or fatty structures, although she felt considerably stronger physically, very much more cheerful in spirits, and more hopeful in mind.

One day I was suddenly called to attend her, and was informed by the messenger that the child had been born almost without any warning of its birth, and before he had had time to leave the house.

On arriving I found the patient lying on her right side, just as she had thrown herself upon the bed, the baby now separated from her, but lying between the legs, and having the cord entangled about its neck and limbs. The nurse mentioned that the child had not cried since its birth.

On examination I found the cord tightly encircling the neck, the upper extremities also being implicated in its coils, so that respiration was performed with difficulty. The child's face was of a livid hue, showing that a very little longer time would have sufficed to occasion a condition of asphyxia. The entire of the body was jaundiced.

When the infant was separated I made the mother turn on her back in order to enable me to grasp the womb, which having accomplished, I desired her to turn over on her left side that I might have the organ more completely under control, and by gentle but telling compressive force expel its contents. The compression was exercised in the usual backward and downward direction, and the afterbirth with all its appendages came away immediately.

When the mother was made comfortable attention was directed to the child. The funis seemed to be quite right. The child was jaundiced all over from the crown of its head to the soles of its feet; and in various parts of the neck, trunk, and limbs were there spots of a bluish-black hue, as if the child had been pinched and bruised. Some of these spots were as large as a penny piece.

Moreover, the child was wretchedly puny, and though perfect as regarded its development, was of a very small size; was thin and ill-nourished; the skin was corrugated and pinched, as if the child had so rapidly lost flesh that the integument was unable to contract proportionately.

For the removal of the jaundice I ordered the child to be put to the breasts as soon as possible, that it might drink the first milk and have a free action of the bowels. In addition, I ordered a little castor oil and minute doses of grey powder.

The infant seemed to be doing as well as could be expected, considering all the ills against which it had to contend. But on the eighth day after birth some oozing of blood took place at that part of the cord where it passes into the abdomen. The funis had not yet come away. To this bleeding the attendant neglected to direct my attention, and it was not till the twelfth day—the day on which the decayed cord fell off—that it was mentioned to me.

Of course the occurrence of such a circumstance never entered into my mind, and I had rested satisfied with Mrs. G. S.'s mother's assurance that "baby was doing all right, except for the jaundice and the bruises." I should have mentioned that delivery had occurred when the patient had accomplished only her seventh month.

The urine of the child was loaded with bile, and dyed everything with which it came into contact. The fæces also were surcharged with bile.

On the twelfth day the hæmorrhage had set in. In the afternoon of the same day I saw the child, and found that not a little bleeding had already taken place, and that the flow was considerably greater than the weakly state of the infant was likely to withstand. I feared, moreover, that efforts to control the loss of blood would be unavailing; owing to the existence of the peculiar diathesis. The following efforts were, however, made:—Cotton wool was laid upon the bleeding surface, at first in a dry state, and afterwards soaked in the muriate tincture of iron. This not succeeding—the several layers having become saturated—the superimposed mass was removed, the blood-covered surface dried, and search made for the bleeding point. There seemed to be not any one particular place, but several spots, whence the blood flowed in such a manner that there was an oozing from the entire surface of the umbilicus, rather than a weeping from one spot.

As the umbilicus was apparently sufficiently prominent to admit a ligature around it, I essayed to deligate it, but failed. First, because that part of the cord, which yet remained attached to the abdomen, was quite decayed, and unable to hold anything upon it; and, secondly, because the umbilicus receded as I endeavoured to tie it. There was now noticeable one point in the lower segment of the umbilicus from which the blood trickled faster than from any other; this I sought to include in the knot of a ligature, but the tissues gave way as I tried to lift them by means of the point of the tenaculum, and I was forced to abandon the procedure.

A dossil of cotton wool was placed over the umbilicus, and upon it was laid a shilling, the finger of an attendant was then made to exercise upon it gentle compression, and the mother of my lying-in patient was set to watch that the compression was properly maintained. I called again in the evening, and had the mortification to find that the cotton wool and shilling had been shifted from their position, that the bleeding had been allowed to proceed without any check, and had, indeed, been rendered more profuse by the pressure having been made about two inches above the umbilicus, which was consequently made more prominent and bulged in such a way that the bleeding was encouraged.

As the child was decidedly weakened by this loss of blood, I resolved to tie either the umbilicus and integument in a mass, or else the integument over the umbilicus, with the hope that the bleeding might be arrested; but before undertaking so painful and severe an operation I had a consultation with Inspector-General Dolmage, who approved of the measure, and kindly lent his assistance.

We found it impossible to lift the umbilicus forward, and it was with no little difficulty that we pinched up even the integument immediately surrounding it. We therefore hooked forward on the point of the tenaculum that portion of the skin of the abdomen which lay directly below the navel, and having dipped the point we managed to seize the navel itself along with the integument above it, and to include all in the knot of the ligature, which was drawn as tightly as possible. Immediately that this was done the child screamed loudly, and very soon showed symptoms of collapse, probably from the shock sustained by the system when the ligature was tightened. This untoward, but foreseen event had in some measure been guarded against by the administration, previously, of a little brandy and warm milk; the same restoratives were given now, but failing to rouse the child, which seemed so depressed as to be unable to take the breast, a mustard poultice was applied to the spine, and the body swathed in a hot flannel which was well wetted with brandy.

These remedies had the effect of rousing the infant; and the pain occasioned by the mustard made it take the breast most eagerly. It continued to cry for some time; at length it again became exhausted. In the course of the night it died.

At the post-mortem examination I found the skin very deeply jaundiced, and abundantly covered with the hæmorrhagic spots; the process of ulceration or of sloughing, by which the funis had become detached, had extended underneath the skin of the abdomen, so that when the ligature was removed the umbilical vessels were quite open, and were now—in the dead state—completely patulous; there was acute peritoneal inflammation immediately surrounding the umbilicus; the intestines had not been wounded in the dipping of the needle.

Should a similar case again occur I should feel disposed to pass two needles through the skin of the abdomen, one above and the other below the umbilicus, and from the left to the right side, so that they should run parallel with each other, and transversely as regards the umbilical vessels. I should next, having penetrated the skin on the left of and above the navel, dip the point of the needle so as to get it underneath the umbilical vessels, and having done so, I should then from within pierce the skin on the right of the navel, and bringing out the point compress the vessels between the needle and the integument. Should this method of compression not answer I should pass the ligature around the needle in the same way as for hare lip, and thus more effectually exercise compression. The same should be done below the navel, so as to obtain occlusion of any bleeding vessels that run below it. Or, if this procedure would not act efficaciously, I should pass two or more needles into the integuments and umbilicus from side to side, and from below upwards, and then employ the ligature in the same manner as I have just described. Of course extreme caution should be observed, lest the bowels should be wounded, or taken up by the needle, and tied in the knot of the ligature.

9, Lupus-street, St. George's-square, Pimlico.

Hospital Reports.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

Dr. LYONS'S CLINIQUE.

TYPHUS SUPERVENING ON TYPHOID FEVER.

(From Notes by Mr. CRAWFORD, Clinical Clerk.)

Case 1.—The patient, aged 25, a policeman, of thin, spare, but vigorous frame, was admitted into hospital, labouring under diarrhœa, on October 23rd, 1866, and remained under treatment until November 8th, when he left hospital, supposing himself well. Two days subsequently,

he was obliged to seek re-admission, and was then placed under Dr. Lyons' care. He suffered much from headache and gastric irritation, with frequent vomiting of a greenish-yellow bilious fluid. The tongue was thickly furred, and on examining the abdomen, a few well-marked rose-coloured lenticular spots were observable. There was no tenderness elicited on careful palpation of the abdomen, but on the day of admission four copious dark-brown liquid pea-soup like stools were passed, and henceforth, diarrhœa with stools of a similar character was a constant feature of the case for many days. He was sleepless, occasionally delirious, and usually much depressed, nervous, and apprehensive about himself. The urine was much diminished in quantity, and eventually to such a degree that it was found necessary to administer diuretics to promote this excretion. The catheter had to be employed daily.

On the 15th November a distinctly new set of phenomena became developed in the case. The lenticular spots faded and gave place to a well-marked and pretty copious eruption of true typhus maculæ well exhibited on the trunk and limbs. Extreme typhic prostration was now manifested; the action of the heart and of the radial pulse was excessively feeble, and abundant stimulation was called for and freely supplied. On the 17th he was attacked with hiccup, which now became the most troublesome, and serious symptom of the case, and continued till the 26th. Ice, sinapisms, and various internal remedies were employed with little or no effect; eventually the following combination was administered with decided result in controlling and eventually mastering this distressing affection:—

℞ Muriatis Morphiæ, gr. ii.
Capsici, gr. iv.
Creasoti, gr. ii.
Ext. gentianæ, q.s. ut fiant. pil. viii.
St. i. 2ndis horis.

On the 27th he was able to pass water himself, and from this period out steadily progressed to convalescence. On looking back over the history of this case, Dr. Lyons regards it as a well-marked example of the supervention of typhus fever upon typhoid, the former supplanting the latter, and thus giving to the case at its close, or in its second phase, its predominant characteristics. It may be assumed that the intestinal lesion received a decided check at the moment of the development of the true typhus state, and gradually progressed through the stages of silent *non-ulcerative* elimination already fully explained in former clinics.

The next case exhibits in a still more marked manner the want of protective influence to the system against the invasion of typhus in a patient who had passed through and to a great degree convalesced from fully-developed typhoid fever.

Case 2.—This case may be briefly summarised. The patient, a boy aged 14, was admitted into hospital and placed under Dr. Lyons' care, in the Hardwicke Hospital, on August 20th, 1866. It will be sufficient to state that he developed in a well-marked degree all the essential and characteristic features of typhoid fever, with much gastric irritation and constant and copious diarrhœa, with frequent pain and uneasiness in the bowels, and ilio cæcal gurgling. It is further worthy of note that he exhibited to an excessive degree the typhic prostration of the system, which alone, as Dr. Lyons has already shown, could have ever led to the confounding of diseases so essentially different, under ordinary circumstances, in general aspect, and marked by such well-defined distinctions to the eye of the pathological anatomist, as typhus and typhoid fevers. A bed-sore formed on the right buttock, as well defined as is ever seen in true putrid typhus. Under careful diet and medication this patient was slowly brought through many phases of imminent peril to convalescence, which may be considered to have been fairly and fully established by the end of about the eighth week after admission. He was still, however, much debilitated, and the bed-sore

not fully closed up, though he was up and about daily. He was now seized with rigors, headache, loss of appetite, and other forerunning symptoms of a new febrile attack, and in due time exhibited a full and copious maculated eruption, while the pulse rose to 132. It was now evident that typhus fever had been implanted in his system, and he went through all its phases as if he never had suffered from any form of typhic disease, and it was thus clearly evidenced that his protracted typhoid fever had given him no immunity whatever against the invasion of typhus. With time, care, and abundant nourishment and stimulation, he convalesced from his second fever, and finally left hospital on the 24th November, after a sojourn of ninety-five days in the institution.

SPECIAL REPORT

ON THE TREATMENT OF CHOLERA BY VENOUS INJECTIONS.

V.

THE EPIDEMIC OF 1866.

(Continued from page 573.)

The table on next page includes all the cases treated during the past summer by Mr. Little in

THE LONDON HOSPITAL.

The table gives ample details of the less interesting cases. We propose therefore only to report in full those which most clearly show the effects of the treatment:—

No. 10 of the Table.

INJECTION OF SALINES; IMPROVEMENT; RELAPSE. RE-INJECTION; IMPROVEMENT; RELAPSE. REINJECTION; RECOVERY.

Case 15.—D. H., aged 28, married, a stout German woman, admitted August 29th at twenty minutes to eight A.M. Taken ill with purging and vomiting of rice-water at twelve last night; has had no premonitory diarrhœa. Her aspect is choleraic, eyes sunken, lips livid, pulse scarcely perceptible. Vomits constantly; has severe cramps in the belly and legs; respiration quick.

At twenty minutes past eleven, much worse. No pulse. Temperature in the axilla 92.2, in the vagina 101; cramps are frightful; respiration 42.

At two P.M. fifty ounces of saline alcoholic fluid were passed into the right median basilic, by gravity, in fifteen minutes. The pulse at once returned, at 98, the cramps lessened; temperature in axilla 95.2, in vagina 100; respiration 36.

Immediately after the injection she had a rigor, so severe that her teeth chattered, and the bed shook. Hot brandy-and-water was given her, which she kept down. In another half hour she got worse again, the pulse weaker, and at twenty-five minutes past three, seventy ounces of the same fluid were introduced into the vein on the opposite side; the pulse improved immensely, she had little pain, and talked freely. Temperature in axilla at four P.M., 102.6.

Seven P.M. No pain, no cramps, no sickness; has been purged four times since two o'clock; takes fluid food; pulse full, 120; temperature 100; profuse perspiration; she was placed on a hot-water bed.

Half-past ten. Temperature 96.2; is easy. Midnight, slightly sick.

August 30th, four A.M. Pulse 120.

Half-past six. Temperature 94; pulse very small and very frequent. Fifty ounces injected into left arm. Afterwards pulse strong and full, 104. Aspect good, lips red. Has had seven more uncoloured stools. Temperature 96; vomits slightly; shivers so that teeth chatter; temperature rising. Takes hot brandy-and-water. Quarter to

In the Table, "Hours ill" means the time since the setting in of urgent symptoms, irrespective of any diarrhoea which may have preceded the attack. The column headed "Death in hours" contains the time in which death took place after first injection.

eight, pulse good, 140. Half-past nine, temperature 100. Half-past ten, temperature 99.2; pulse 130. Three P.M., temperature 97.2. Seven P.M., temperature 97; pulse 96.

31st. Going on well, complains only of headache. A blister was applied to the neck and gave relief. Takes fluid food, and ten drops of aromatic spirits of ammonia, every half-hour. She went on convalescing slowly; her first urine was passed, September 2nd, at four A.M., (there had been none for one hundred hours). Discharged cured September 17th. Diet, chops and wine allowance.

No. 11 of the Table.

INJECTION; CONVALESCENCE; RELAPSE. DEATH ON THE SIXTEENTH DAY.

Case 16.—W. L., of Shadwell, a small, weakly man, the father of the subject of Case 9 of the table, was admitted August 29th, at ten A.M. Was quite well until twelve last night (though his bowels have been rather loose for three weeks), when he was seized with continuous purging of stuff like slaked lime. Has not vomited but felt sick, has made water this morning. On admission his eyes were sunken, but the skin was warm, the pulse fair, the tongue foul. At twelve noon, surface cold; pulse feeble; respiration hurried; has severe cramps in the legs and belly; no purging, vomiting, or passage of urine; at two P.M., much worse, he is scarcely sensible; voice very choleraic, a faint whisper. Temperature in axilla 96.4. Fifty ounces of saline alcoholic fluid were injected into a vein at his elbow, after which his pulse was good and his temperature rose, and his breathing was easier. At seven P.M., has been purged three times, profuse perspiration; is sleepy; pulse good, 120; temperature in axilla 99.4. Has had no cramps since the injection, takes beef-tea.

August 30th. Twenty minutes to seven A.M. Pulse 94, soft and full; temperature 97.8. Has passed five brownish fluid motions, during the night, and been sick twice. Feels comfortable, looks convalescent, and takes food. Six P.M., temperature in axilla 97.4, pulse 88.

31st. First urine at three A.M.; is quite convalescent.

September 1st. At two A.M., was much frightened and shocked by a patient with delirium tremens, who was being removed from the ward at six P.M.; was prostrate, much purged, and almost dying, not livid or choleraic. At half-past one much the same; four stools to-day; ordered saline, and brandy enema every two hours; he keeps them up. Takes beef-tea and brandy-and-water.

2nd. Rather stronger, still slightly purged.

3rd. A little better.

4th. Worse again, has been frequently purged, aspect choleraic, eyes sunken. Begs not to be injected again; has taken astringents and chalk without effect on the purging. Death at two P.M. The post-mortem examination presented no peculiar appearances, with the exception of very large kidneys, but apparently healthy. For two days after the injection, this patient was so well that Mr. Little had no doubt as to his recovery, and still believes reinjection would have saved him.

No. 12 of the Table.

INJECTION OF SERUM; IMPROVEMENT; RELAPSE. DEATH ON THE THIRD DAY.

Case 17.—Thomas C., aged 64, of Spitalfields, was admitted on the morning of August 31st. Had had looseness of the bowels for a fortnight or more; taken at three A.M., this morning with purging and vomiting of a rice-water character, and severe cramps in arms, legs, and belly. On admission, his aspect was choleraic; lips and hands livid; pulse perceptible. At half-past two much worse; temperature in axilla 95; hands much shrivelled and blue; no pulse; vomiting most profuse. Forty ounces of serum, from sheep's blood, were injected; the serum was from the blood of a sheep killed that morning. After the blood had stood six hours, the serum was poured off and filtered. After the operation the patient had a most severe, violent, and prolonged rigor. Hot brandy-and-water was given him, and he was placed on a hot-water bed. At six P.M., he was sweating profusely, was not sick; had no cramps; colour good. Tempera-

ture 101·2 in axilla. Takes warm fluids readily. Seven P.M.—Sleeps; no cramps, vomiting or purging, since the injection. Half-past eleven.—Has slept off and on, and had one rice-water stool.

September 1st. Going on well; two stools; temperature axilla 99; takes fluid food.

2nd. Not so well, breathing hurried. Two P.M.—Respirations 55; pulse good, 130; is dying. Death at eight P.M.

An examination of the body was made sixteen hours after death; there was no congestion about the heart or great vessels, but the lungs were filled with blood, particularly their bases. The intestines contained a quantity of brownish fluid, and there were ulcerations of Peyer's patches. The bladder contained two ounces of dark urine. On examination of the blood with the microscope, the discs seem more plump than usual, none were broken. This patient was doing so well on the second day, that I thought he would recover. He died in reaction.

No. 13 of the Table.

INJECTION OF SALINES; IMPROVEMENT. RELAPSE; RE-INJECTION; RECOVERY.

Case 18.—M. L., æt. 20, of Hackney, admitted at half-past four P.M., on the 31st of August; taken ill at six A.M., with purging and vomiting, cramps in the legs and belly; no urine since last night. On admission, her surface was cold; aspect somewhat choleraic; pulse very small. She was put on the calomel treatment, with large doses. Quarter-past eight P.M.—Much worse, continues rice-water purging and vomiting; pulse only perceptible, now and then; temperature in axilla 93, in the vagina 99. She got worse, and at half-past two A.M., on the 1st of September, had no pulse; hands and lips were livid; and fifty ounces of saline alcoholic fluid were injected with good result. At three A.M., temperature in axilla 98. She had a slight rigor after the injection. At half-past seven A.M., no pulse, respiration 38, temperature 94, so seventy ounces were injected into the same vein. A larger quantity was put in this time, as improvement did not take place so rapidly. She vomited after the first pint; and, at the close of the operation, her temperature had risen to 97, her pulse was restored, and her respiration had fallen to 34. At nine A.M., in profuse perspiration, feels well. Seven P.M., has felt well all day; no purging or vomiting; temperature in axilla 97; pulse good, arms and hands cold and wet from sweat; was placed on hot-water bed; takes fluid food readily.

September 2nd. Much better; has a headache; a blister was put to the back of the neck, and she was relieved in half-an-hour.

3rd. Convalescent.

19th. Is strong and well, and is to go into the country.

No. 14 of the Table.

INJECTION OF SALINES; IMPROVEMENT. RELAPSE; RE-INJECTION. RELAPSE; REINJECTION; RECOVERY. 240 OUNCES IN ALL.

Case 19.—J. S., of Whitechapel, aged 40, admitted September 10th, at quarter to nine P.M.; has been living badly, and out of work lately; was taken ill at six P.M., with purging and vomiting of a rice-water character, and cramps in his limbs. When admitted he was cold, and pulseless; lips and hands livid; cold perspiration on the forehead; no voice. No urine since the morning; temperature in axilla 96.

September 11th.—Two A.M., worse; lips and face awfully blue; hands also, as blue as any patient that has been in the hospital; vomiting and purging profuse; temperature in axilla 95·2; eighty ounces of alcoholic saline fluid introduced in fifteen minutes. At the conclusion of the operation, breathing easier; pulse 100; temperature in the axilla rose to 99·4, with a slight rigor; likes hot brandy-and-water. Half-past eleven A.M.—Has had one small stool since injection; no cramps or pain;

voice a faint whisper; no radial pulse; carotid 120; temperature 96. At noon, eighty ounces were again put into his veins, with immediate improvement; says "he breathes freer;" is lively and talkative; hopes I shall re-inject him if he gets worse; lips natural colour, face pale. One P.M., has had no rigor, but says he feels cold; temperature in axilla 102; some purging continues, but no vomiting. Two P.M., in a healthy sleep; respiration 96, pulse 90. Six P.M., profuse perspiration, tongue cold; says he is hot, pulse small. Nine P.M., no pulse, aspect choleraic again; eighty ounces were again introduced, after which he improved wonderfully; said he was sleepy and went to sleep.

12th. Has not slept much, but was rather delirious; takes food; is much better; talks freely; pulse 98, temperature 98, respiration 26. Quarter past eight P.M.—One stool since the morning, no sickness, takes his food well; respiration 20, pulse 120, temperature 97.

13th. Has had two or three slight shiverings, but feels warm; no purging or vomiting; first urine to-day.

19th. Has gone on improving; is now convalescent.

No. 15 of the Table.

INJECTION OF SALINES; IMPROVEMENT. RELAPSE; RE-INJECTION; RECOVERY. DEATH FROM SYPHILIS.

Case 20.—M. H., aged 35, a thin spare woman, was admitted September 11th, at ten A.M.; has had looseness of the bowels for two days. Was taken ill in the night with rice-water stools, and cramps in the legs and belly. On admission, the choleraic aspect was extremely marked; respiration 30, pulse scarcely perceptible; has passed no urine for two days. Ten minutes to twelve A.M.—Pulse sometimes perceptible, about 80; lips, tongue, and hands livid; voice very feeble; vomits much; no purging since admission; the abdomen is dull, and contains a quantity of fluid, which rattles when shook. Half-past one.—Collapse extreme; temperature 93; no pulse; could not be roused to consciousness; eighty ounces of saline alcoholic fluid were injected. As the injection proceeded, consciousness and voice returned, and a pulse at 100; the breathing became easier and less frequent, and she talked, and wanted to know how she got ill. At two P.M., she vomited, and was purged for the first time since admission; temperature 97. Six P.M.—Profuse perspiration; pulse scarcely perceptible. Nine P.M., collapsed again; temperature 95; eighty ounces were again injected, with only slight immediate benefit, but in half-an-hour the pulse became fair, at 104; temperature 98.

September 12th.—Ten A.M., pulse good, patient much better altogether; surface warm, aspect natural; has slept well, and taken two ounces of brandy. Quarter-past three, doing well; pulse 96, respiration 24; no motions, vomits when she takes food.

13th.—One A.M., complains of pain in the belly, is rather restless, has headache; ordered, turpentine to the abdomen, and effervescing saline mixture, with hydrocyanic acid. Ten A.M.—Six ounces of urine drawn off; pulse 96, respiration 25.

19th.—Has gone on improving, and is now convalescent. This patient died on the 29th with syphilitic ulcerations of the rectum and throat.

(To be continued.)

THE oldest known British crab (*Palæinachus*) is figured and described by Mr. Henry Woodward in the *Quarterly Journal of the Geological Society* (No. 88, p. 403). It appears with nearly all its limbs *in situ*, showing the carapace with four segments of the abdomen united to it, resting upon a slab of the forest marble of Malmesbury, Wilts, covered with remains of Pentacrinis, &c. The limbs are long and slender, and in some respects, such as the carapace with remarkably prominent tubercles in front, it closely resembles the common spider crabs living on our coasts. In the swollen form of the branchial regions and the nuchal furrow, it resembles the *Inachus*, with which it agrees in the form and proportion of its limbs; hence its name.

Foreign Medical Literature.

ON THE TREATMENT

OF HEMOPTYSIS WITH INHALATIONS OF LIQUOR FERRI SESQUICHLORATI [SESQUICHLORIDI].

By Dr. P. Q. BRONDGEEST.

Translated from the *Nederlandsch Archief voor Genees- en Natuurkunde*, Deel ii. 2e Aftoering.

By WM. DANIEL MOORE, M.D. Dub. et Cantab., M.R.I.A.,

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS, OF THE NORWEGIAN MEDICAL SOCIETY, AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; EXAMINER IN MATERIA MEDICA AND MEDICAL JURISPRUDENCE IN THE QUEEN'S UNIVERSITY IN IRELAND.

THE local treatment of morbid affections of the air passages, by the inhalation of fluids in the state of vapour, has latterly been very extensively adopted. In no department can we, however, point to such excellent results as in the treatment of hemorrhage of the respiratory passages by means of styptic inhalations. The most important observations on this subject are undoubtedly those of Fieber,* both on account of the fulness of detail with which they are communicated, and of the success with which the treatment was crowned. We fully endorse what Fieber says as to the value of this method: "If the mode of treatment by inhalation by means of pulverisers had," he says, "no other merit than that of rendering possible the direct application of hemostatics to the bleeding points or their immediate vicinity, this would suffice to ensure it an honourable place in therapeutics. Not only is one of the most dangerous symptoms often directly removed by the inhalation of styptics, but the dictates of humanity to free the patient from an affection which renders him most uneasy, and fearfully rouses phthisical patients in particular from the consoling illusion of improvement which nature lends them to lighten their sickness, are most rapidly and effectually fulfilled."†

Fieber's observations led me to form the resolution to adopt this mode of treatment when opportunity should present itself.

I shall now communicate the results obtained in three cases.

For pulverizing the fluid Bergson's well-known apparatus was employed, which on account of the facility of using it and its portability deserves to be preferred to any other.

Case 1.—On the 3rd Nov., 1861, I was called to see Heer de H., aged 57, the head of an extensive stonemasonry establishment, who had for a year previously been under my care for pulmonary tuberculosis. The patient from time to time expectorated small calcareous concretions, and daily a large quantity of yellowish sputa, sometimes mixed with slight streaks of blood. From the physical examination of the chest, I inferred the existence in the apex of each lung of a cavity, according to my opinion in process of healing; in favour of which were the facts that the dulness on percussion was not extending; that the cavernous râles were very weak, sometimes not perceptible; and that, moreover, as has already been mentioned, calcareous concretions were expectorated, while the sputa appeared to me to be thick, and but slightly purulent. I found the patient lying in bed in a state of great anxiety and exhaustion. Those about him informed me that an hour and a half previously, while sitting in the water-closet and straining violently, he had suddenly thrown up an enormous quantity of blood, at the same time they showed me a spittoon half filled with bright red blood. Before my arrival the patient had been put to bed, and

the discharge of blood had ceased, only some bloody phlegm was now brought up. The pulse was very small, and below the left clavicle strong râles were audible. I prescribed alum with laurel water internally, and cold compresses to the left side of the chest. In addition, I forbade his speaking, and recommended light diet, and that he should, as much as possible, avoid moving.

During the three following days his state was rather favourable; there was no fever, the sputa expectorated in the course of the third day were only very slightly tinged with blood.

In the night between Sunday and Monday I was called to him at half-past two. The person who awoke me stated that spitting of blood had again taken place. I brought with me Bergson's Inhaler and a solution of one drachm of sesquichlorate [sesquichloride] of iron in eight ounces of distilled water, as I suspected that it would be necessary to make the patient inhale this fluid in the form of vapour. I found him coughing, and each time bringing up bright red blood, while a considerable quantity was already in the spittoon. With the greatest care he was lifted out of bed and placed in an easy position on a chair. The inhalation of the styptic was commenced, and was continued with many intermissions, until the patient expectorated only bloody phlegm. During the inhalation he coughed but little, the hemoptysis was not for a moment aggravated by it. I left him, advising that every two hours he should very slowly make thirty inhalations. Next day I found that no further hemoptysis had taken place, only bloody sputa were expectorated, which continued for four days, while a solution of one drachm of crystallized sesquichlorate of iron in six ounces of distilled water was used for inhalation, a decoction of rhatany being at the same time prescribed for internal use. The patient's strength, however, diminished very much, so that on Friday morning—that is the fifth day after the second attack of hemoptysis, I advised that the inhalations should be discontinued, the more so as they appeared not to be so necessary, the sputa having already begun to be less bloody. At two o'clock in the afternoon of the same day the patient suddenly raised himself upright in the bed, which was immediately followed by violent spitting of blood. When I visited him two hours later I found him in a sad state, very depressed, crying, exhausted, with a small pulse, complaining of oppression, with a glass half filled with blood at his side, and bringing up blood from time to time. In the left infra-clavicular region very loud râles were again perceptible. As taking the patient out of bed was not to be thought of, I caused him to inhale for a considerable time, while in bed, the solution of one drachm of sesquichlorate of iron in six ounces of distilled water, until the spitting of blood had ceased, and to continue this every two hours. At half-past eleven in the evening I found his breathing very much oppressed, with loud râles, so that I thought I should not find him alive next morning. The inhalations were continued every two hours during the whole night. The following morning I was very much rejoiced to find that no more spitting of blood had occurred, and that after the inhalations only bloody phlegm was expectorated. The inhalations were continued, with the internal use of rhatany, three times a day until thirty had been employed. The red colour of the sputa disappeared, the strength gradually increased, and now, after the lapse of six weeks, no hemoptysis has taken place. Although still keeping his room, the patient is already beginning to discharge some duties of an administrative nature, and is getting into a state similar to that he was in before the first hemoptysis occurred.

Case 2.—Miss M., aged 35, a native of Neufchatel, in Switzerland, governess in the family of F., at the Bilt, near Utrecht, came to consult me in the month of May for a laryngeal affection. She complained of sore throat, cough, shortness of breathing, and want of sleep. She had daily an attack of fever. She was very anxious about her state, as her father had died of laryngeal phthisis. On laryngoscopic examination I found that the signs of a chronic

* *Wiener med. Wochenschrift*, 1863, Nos. 49, 50; 1864, No. 27; 1865, Nos. 5, 6, 7, and 8.

† *Die Inhalation medicamentöser Flüssigkeiten*, etc. von Dr. Friedrich Fieber, p. 133.

laryngeal catarrh, general redness, and slight mucus secretion were present; no ulcerations were perceptible. In the infra and supra-clavicular regions was a very feeble respiratory murmur; the sound on percussion was clear; the resonance of the voice presented no difference on either side. I prescribed the use of sulphate of quinia, and at night a morphia powder. After some days she returned and informed me that she had in the morning spit blood, about two teaspoonfuls, and that this had taken place also some months before. Her former attendant assured her that this was not connected with any injury to her health, and therefore she paid little attention to it. Again, examining the chest, I observed neither râle nor crepitus; the heart's impulse was very strong, and the cardiac sounds were distinct and audible over the whole chest.

I suspected that the cause of the hemoptysis lay in a tubercular process in the lungs, although I had observed no decisive physical signs in favour of this view. I made her use, for a week, inhalations of tannin dissolved in water, but without any apparent effect, for which reason I replaced this solution with one of a drachm of crystals of sesquichlorate of iron in ten ounces of water, as she could not inhale a strong one. I advised her to continue this for a week, making fifteen inhalations three times a day. The spitting of blood soon ceased. I made her continue the inhalations for some time, and heard no more of the patient until the end of the month of May, when she again called on me and stated, that after having spent some time at the Hague, where she had taken much exercise and had exceedingly fatigued herself, the spitting of blood had returned. I found her very much emaciated; her pulse was weak, and her face very pale. I advised her to continue the inhalations steadily, with a solution of one drachm to eight ounces of water; the result was that the spitting of blood soon ceased again. Seeing her once more in August I found her state remarkably improved; she had for two months had no return of the spitting of blood. Towards the end of August it recommenced, which she communicated to me in writing, whereupon I again sent her the inhalation apparatus. In a letter dated September 22nd, she again gave me a report of her state. On this occasion the hemoptysis had been very obstinate, nevertheless it finally yielded to the diligent use of the inhalations, which she continued for a considerable time after its cessation. "Now I feel," she wrote to me, "very well, and I can do much without being fatigued; it even appears to me, that I can breathe much more freely than I have for a long time been able to do." From this period I heard no more of her; but, as she has not since got the inhalation apparatus from me, I may infer that the hemoptysis has for four months not returned.

Case 3.—Miss C. N. de T., aged 25, applied to me in the month of May, on account of hemoptysis, from which she had suffered during the preceding six months. She seemed not to think much of her illness, for she required persuasion to induce her to seek for medical aid. She expectorated blood at very irregular periods. At one time the hemoptysis occurred every day, at another there was an interval of fourteen days. The quantity amounted to half a teacupful; the blood came up with a slight cough. Her chest was very flat, but no certain signs of pulmonary tuberculosis existed. After she had inhaled for some time, about fourteen days, a solution of crystallised sesquichlorate of iron in distilled water, the hemoptysis ceased. It has not returned during the last six months. Liquor stypticus, internally administered, had no effect.

The cases here communicated prove that very obstinate bleeding from the air-passages may be arrested by the inhalation of a solution of chloride of iron. They, moreover, show that the inhalation in itself does not give rise to any temporary aggravation of the symptoms, and that if some precautionary measures be taken (to have the solution not too concentrated, and the distance of the patient from the inhaling apparatus not too short), neither is the cough excited by it. I believe that where medical assistance is

called to a case of dangerous hemorrhage from the air-passages, this mode of treatment should be immediately employed, and that every physician ought to have the proper apparatus ready at hand, by means of which he can control such a dangerous symptom, and by so doing, probably save or prolong many a life.

Utrecht, 28th December.

SUMMARY OF SCIENCE.

(Specially Edited and Compiled for the Medical Press and Circular.)

By CHARLES R. C. TICHBORNE, F.O.S.L., F.R.G.S.I., &c.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

GRAHAM'S RESEARCHES ON THE ABSORPTION AND DIALYTIC SEPARATION OF GASES BY CAOUTCHOUC FILMS.

A THIN film of caoutchouc has no porosity, and is really as impervious to air as gas; but it is capable of liquefying the individual gases of which air is composed, while oxygen and nitrogen, in the liquid form, are capable of penetrating the substance of the membrane (as ether or naphtha does), and may again evaporate into a vacuum, and appear as gases. The gases are, however, unequally absorbed and condensed by the rubber—oxygen two and a half times more abundantly than nitrogen, and they penetrate the rubber in the same proportion. Hence, a sheet or septum of rubber may be used as a dialytic sieve for atmospheric air. The septum keeps back one-half of the nitrogen, and allows the other half to pass through with all the oxygen. This dialysed air rekindles wood, burning without flame, and is, in fact, exactly intermediate between air and pure oxygen gas in relation to combustion. In this paper the author also refers to MM. Sainte Claire Deville and Troost's experiments with regard to the surprising penetration of platinum and iron tubes hydrogen gas. Platinum and palladium condense hydrogen freely upon their surfaces, but have not the slightest absorbent power for either oxygen or nitrogen. Carbonic oxide is taken up more largely than hydrogen by soft iron. Silver has a similar relation to oxygen, of which metal the sponge, fritted, but not fused, was found to hold in one case as much as 7.40 volumes of oxygen. A plate or wire of the fused metal retains the same property, but much reduced in intensity.

PHYSIOLOGICAL PROPERTIES OF THE AMYL COMPOUNDS, FROM DR. RICHARDSON'S REPORTS.

On inhalation of nitrite of amyl, great stimulation and increased action of the heart follow. The author could make any number of persons' hearts quicken ten beats per minute by the aid of nitrite of amyl vapour.

Acetate of amyl (essence of pears) was an excellent antiseptic.

Pure ether was preferable as an anæsthetic to the following:—acetic æther, hydrochloric æther, nitrite of amyl, amylen, or chloroform.

Nitrite of ethyl, like nitrite of amyl, was one of the most powerful excitants of the heart. Amylene and æther produce their effects by virtue of two acts—by suppressing oxidation of the blood in the lungs, and by the extraction of caloric from the blood. This latter point was advanced as a new and more simple explanation of the action of the substance named, than had been before suggested. That the modification of symptoms produced by the change of form of a simple amyl or ethyle compound into a nitrite, turned upon the introduction of nitrogen into the composition, and by this introduction the anæsthetic action is destroyed, and is replaced by disturbance of muscular action, especially of the heart. In this respect the nitrite compounds represent immediately, in an exaggerated degree, the action of strychnine, theine, nicotine, and analogous alkaloidal substances, of which nitrogen forms an elementary constituent.

BORONATROCALCITE A SOURCE OF BORAX.

We meet in Chili, says M. G. Lunge, a mineral having the following composition:—

This mineral dissolves in acids to a limpid solution, so that its constituents can be estimated at once by the ordinary means. It is used for making borax.

ON THE INFLUENCE OF WATER AND AQUEOUS FOOD IN THE PRODUCTION OF MILK.

M. Dancel shows, by a series of experiments, that water or aqueous food favours the production of milk in the herbivores, and that if we wet their dry food, or induce them to drink, by adding a little sea salt to their water, we shall obtain a more considerable quantity of good milk, but the butter will not be so firm or white.

A cow that does not drink thirty litres of water per day (about six and three quarter gallons), only gives from six to eight litres of milk; whilst a cow that will drink sixty litres of water will give twenty to twenty-five litres of good milk. The author does not, however, give the analysis of the milks in the different experiments.

ON THE TOXICOLOGICAL ACTION OF PHOSPHORUS.

Wahler and Frerichs attribute the poisonous effects of phosphorus to its transformation, in the economy, into phosphorus and hypophosphorus acids. Munk and Leyde said it was converted into phosphoric, but the symptoms produced by phosphoric acid do not accord with those produced by poisoning with phosphorus. Most of the physiologists admit that the phosphorus is absorbed by the blood. 1st. The author finds that defibrinated blood left in contact with phosphorus does not show any other modification than those which result from the absorption of oxygen and the ulterior action of the phosphoric acid, formed by the action of the oxygen contained in it. This is avoided by adding carbonate of soda. 2nd. Blood, deoxidized by oxide of carbon, is not altered by contact with phosphorus. 3rd. Phosphorus, dissolved in oil and injected into the blood, does not produce the same symptoms as when it is introduced through the digestive organs. 4th. The breath of an animal poisoned with phosphorus blackens, after some time, paper dipped in nitrate of silver. It is, therefore, evident that part of the phosphorus absorbed escapes in part as phosphuretted hydrogen. The author puts the question—Is not the poisonous properties of phosphorus due to its conversion into this gas? He seeks to show that the symptoms of poisoning by phosphorus are identical with those produced by inhaling the gas (not spontaneously inflammable). Phosphuretted hydrogen acts upon the blood by extracting its oxygen, and it then presents the same physical properties as deoxidized blood, and contains a considerable quantity of phosphorus acid. Arterial blood is able to absorb 26.73 per cent. of its volume of gas; venous blood only 0.13 per cent. In the pressure of aerated water rendered alkaline, gastric juice, and blood, phosphorus produced considerable quantities of phosphuretted hydrogen in a very short time.

M. Blondlot (*Journal de Pharmacie*) says that phosphorus acts directly in the state of vapour, and that this subtile poison penetrates slowly through the system.

WHEAT PHOSPHATES.

Under this name a food is procured which may be of great use to delicate children. A decoction of bran is evaporated to dryness with sugar and powdered. This preparation contains a great quantity of the phosphates; the middle of the grain consists almost entirely of starch; but it is in the corticle envelope that the greater proportion of the salts are found, particularly the phosphates.

ACTION OF WATER ON HYDRATED SESQUIOXIDE OF IRON.

M. Davies notes the fact that hydrated peroxide of iron is partially dehydrated on boiling it in water, and that on submitting it to a temperature of 60° C. for 2000 hours it becomes nearly insoluble in nitric acid.

ON THE REMOVAL OF NITRIC ACID FROM SULPHURIC ACID BY CHARCOAL.

The following is taken from a communication from W. Skey (Geological Survey, New Zealand) to the editor of the *Chemical News*:—In certain analytical operations it is sometimes necessary to use sulphuric acid which is uncontaminated with nitric acid, but their separation has hitherto been a matter of difficulty, only attained by methods of a very protracted nature. In the case of diluted sulphuric acid, however, this can be effected, according to the author, by shaking it up with a little freshly-burned charcoal, in a state of powder, for a few minutes, and afterwards filtering.

Sulphuric acid which has been passed through this operation does not give any reaction of nitric acid when left in contact with crystallized sulphate of iron, although before the action may have been very decided. Charcoal, however, does not remove nitric acid from the concentrated acid.

M. FREMY'S EXPERIMENTS UPON THE CRYSTALLIZATION OF INSOLUBLE COMPOUNDS.

It occurred to the author that if he could effect in a very slow manner the precipitations and decompositions which, in the laboratories, produce amorphous bodies, owing to the instantaneity of their formation, he might succeed in obtaining them in the crystalline form. In some experiments the two bodies were introduced into liquids of different density containing gum, sugar, gelatine, &c.; in others, the phenomenon of endosmose was had recourse to; in other trials, wood or unglazed vessels were employed, the result in almost all cases being that he obtained in the crystalline form such insoluble bodies as sulphate of baryta, sulphate of strontia, carbonate of baryta, carbonate of lead, sulphate of lead, oxalate of lime, borate of baryta, chromate of baryta, magnesia, and several sulphides.

PHYSIOLOGICAL ACTION OF NITRATE OF METHYL-STRYCHNINE AND CURARA OR ARROW POISON.

M. Schroff has confirmed the curious fact noticed by M. Stahlsmidt, of the perfect harmlessness of methyl-strychnine when introduced into the blood, but he finds that its action is different when this base is put into direct communication with the blood by subcutaneous injection, for in this case it recovers the poisonous properties which characterize strychnine. This reminds the author of the action of curara, which is similarly digested without danger; and he asks whether this Indian arrow poison may not be of an analogous nature. The experiments have been made on rabbits and frogs.

POISON OF THE SALAMANDRA MACULOSA.

The venemous secretion of the salamander, says M. Zalesky, is obtained in the form of a creamy liquid on scraping with the bark of scalpel the posterior parts of the head and the back of the animal. The liquid which exudes is white, viscid, strongly alkaline, and bitter. It contains a number of globules, which disappear upon the addition of alcohol, ether, or acetic acid. The author separates from this an organic base (which he calls salamandrine), it is procured by precipitation with phospho-molybic acid. It is soluble in water, and has a strong alkaline reaction. It is crystallizable, and when dry may be preserved a long time. It gives salts with acids. The composition is given as $C^{34}H^{60}N^{2}O^5$. It is a virulent poison, and provokes the same symptoms as the natural secretions.

SOLUTION OF PERNITRATE OF IRON.

Messrs. T. and H. Smith recommend the solution of pernitrate of iron to be made by dissolving the pulpy precipitate of peroxide of iron in the proper quantity of nitric acid. They make a solution of perchloride of iron, according to the directions given in the British Pharmacopœia; they then precipitate with ammonia and wash by decantation. As this precipitate contains too much water the excess is removed by pressure; the pulp should measure thirty ounces, and it then dissolved in a proper quantity of diluted nitric acid, 56 parts or 2eq. of the iron require 3eq. of absolute nitric acid, or 162 grains.

The product should be made to measure sixty ounces. The oxide should be added to the acid, not the acid to the oxide, or a basic salt is found.

ON THE ACTION OF THE ELECTRIC CURRENT UPON OZONIZED WATER.

"Cosmos" notices some curious experiments by Prof. Horn of Munich. On sending the current from an electric machine, the plate of which was more than three feet in diameter, through a glass of ozonized water, it was found to be saturated with some compound of cyanogen. This water if drank produces all the symptoms of cholera. This disease, which is produced artificially, is instantly stopped by drinking water saturated with ozone.

THALLIUM PERCHLORATES.

Prof. Roscoe says that perchlorate of thallium is isomorphous with the potassium and ammonium salts. The anhydrous salt is deposited in colourless well-defined rhombic

crystals; they dissolve in three-fourths of their weight of boiling water, and in ten times their weight of water at ordinary temperature. It is but slightly soluble in water.

ARSENATE OF IRON.

M. F. G. Willstein has written an article upon the results of some experiments upon this salt. He says that its composition is the following:—

The author is not certain of its constant composition. He makes it by precipitating arseniate of soda with sulphate of iron; but as the arseniate of soda has the composition HO 2NaO, AsO_5 , we think the author would have probably been more successful if he had followed the directions given in the British Pharmacopœia—that is to say, at least in getting a compound of a more constant construction. The formula given in that work is 3FeO, AsO_5 , and one equivalent of acetate of soda is used to saturate the equivalent of sulphuric acid, which otherwise would be liberated:—

As arseniate of iron is slightly soluble in acetic acid, a better plan would be to use an equivalent of carbonate of soda.

ON THE SEPARATION OF LEFT-HANDED AND RIGHT-HANDED TARTRATES BY MEANS OF SUPERSATURATED SOLUTIONS.

M. Gerney's supersaturated solution of left-handed double tartrate of soda and ammonia does not crystallise in contact with a fragment of the same salt, right-handed and *vice versa*. From an inactive supersaturated solution of double racemate of soda and ammonia—a fragment of right-handed crystal determines only the precipitation of right-handed crystals, whilst a portion of the same liquid in contact with a left-handed crystal produces a deposit of the left-handed salt. This supplies a simple means of separating at will from the double racemate of soda and ammonia either of its two constituent salts.

Reviews.

HISTOLOGICAL DEMONSTRATIONS: a Guide to the Microscopical Examination of the Animal Tissues in Health and Disease, for the Use of the Medical and Veterinary Professions. Being the substance of Lectures delivered by George Harley, M.D., F.R.S., Professor in University College. Edited by GEORGE T. BROWN, M.R.C.V.S., Professor of Veterinary Medicine. Pp. 268. London: Longmans. 1866.

MR. BROWN states in his Preface that the publication of these Demonstrations was suggested to him by an attendance on Dr. Harley's Course of Lectures, delivered in the Physiological Laboratory of University College, during which he observed the facility with which objects were prepared for examination in the presence of the class, and the readiness with which the directions of the demonstrator were comprehended and carried into effect by the students. Hence he conceived the possibility of describing, in an intelligible manner, this method of instruction; and with Dr. Harley's concurrence and the assistance of that gentleman's original notes, the work was undertaken. The plan of the book comprises—first, the construction of the microscope; and secondly, the methods of using it, and then the mode of preparing objects for examination; and lastly, the different organs and tissues are described under their different heads, and in every instance a figure or diagram is given, which the observer is enabled to compare with the specimen. The illustrations are therefore extremely numerous, and we may add that they are all very well executed. Most of them are stated to be drawn from objects prepared exactly in the extemporaneous method directed in the demonstrations, but some are taken from other sources, especially from Kölliker's large work on microscopical anatomy. They constitute, in fact, a complete compendium of histology, the microscopical structure of most forms of life, both healthy and morbid, being successively presented to view, and numerous as are the books devoted to the display and description of microscopical

objects, we know of none which will prove more useful to the student and the practitioner than the present.

DIABETES: its Various Forms and Different Treatments. By GEORGE HARLEY, M.D., F.R.S., Physician to University College Hospital. Pp. 74. London: Walton and Maberley. 1866.

ALBUMINURIA, WITH AND WITHOUT DROPSY: its Different Forms, Pathology, and Treatment. By GEORGE HARLEY, M.D. Pp. 61. London: Walton and Maberley. 1866.

BOTH these works have already appeared in print in the pages of a contemporary medical journal, and their contents form a part of the course of lectures on the urine and the diseases of the urinary organs, which Dr. Harley has been in the habit of delivering annually to medical practitioners since the year 1856. They contain a very lucid account of the respective maladies of which they treat, the chemical characters of the urine being carefully and accurately described, and the pathological conditions being indicated with equal fulness and precision. The treatment of diabetes and albuminuria, as is too well known, is often unsuccessful, and where the result is otherwise, the circumstance is in a great measure due to the skill and discrimination exercised by the medical practitioner, who must not only be fully acquainted with the indications afforded by the microscope and the test-tube in the examination of the urine, but also with the chemical, vital, and pathological changes of which the state of this fluid is one of the exponents. Dr. Harley's observations on treatment will be read with great interest and profit, and the practitioner who takes them as his guide will not find his confidence misplaced. We should mention that these little volumes are very well got up, and reflect great credit on the publishers.

ON THE NATURE, CAUSE, AND TREATMENT OF TUBERCULOSIS. By HORACE DOBELL, M.D., Physician to the Royal Infirmary for Diseases of the Chest, &c. Pp. 84. London: Churchill and Sons. 1866.

ON WINTER COUGH, CATARRH, BRONCHITIS, EMPHYSEMA, ASTHMA; with an Appendix on some Principles of Diet in Disease. By HORACE DOBELL, M.D. Pp. 182. London: Churchill and Sons. 1866.

THE first of these works consists of a series of papers which have appeared at different times in the columns of some of the medical journals, and they are collected together and placed in order, so as to present a consistent view of the theoretical opinions which Dr. Dobell has formed on the subject of tuberculosis. The theory, or rather the hypothesis (for so he himself terms it), framed by Dr. Dobell maintains that tuberculosis is due to a dejective action of the pancreas on the fat, and especially the solid fat, taken as food. The supply of properly prepared fat is cut off from the blood—1st, by the fats not being brought into a proper condition by the pancreas; and 2nd, by loss of absorbing power in the small intestine, due to the contact of unhealthy pancreatic juice and of dejectively prepared food with its mucous membrane. Thus the blood, according to Dr. Dobell, becomes insufficiently supplied with fat elements from the food, and is unable to afford these required for direct combustion, and while it fails to replace those taken up during interstitial nutrition, it takes up more from the food to compensate the deficient supply. This having gone on up to a certain point, the fat elements of the albuminoid tissues are seized upon, and these tissues are minutely disintegrated in the process, and this disintegration is tuberculation, and the disintegrated albuminoid tissues is nascent tubercle. Tuberculation will therefore ensue wherever there is the greatest activity of interstitial nutrition and the smallest amount of fat elements able to be spared by the tissues, and when a double process is going on consisting of—1st, an ordinary interstitial nutrition in albuminoid tissue; and 2nd, interchange of oxygen and carbonic acid, or carbonaceous matters through this tissue.

We have given Dr. Dobell's hypothesis almost in his own words, and while admitting its ingenuity, we must observe that it is not in every instance quite clearly expressed, and that the conclusions are not always quite apparent, at least at first sight. It must also be remarked that there is no very direct evidence that the pancreas is really and neces-

sarily diseased in cases of tuberculosis, as most of the existing information on this point is of a negative character, and Dr. Dobell invites further inquiry into the subject by those who have the leisure or the opportunity to make it. If, however, his views on the nature of tuberculosis are correct, then his treatment, consisting in the administration of fats, and more especially of the pancreatic emulsions of solid fat, is the most satisfactory that can be devised; and we are assured that by the latter plan a great number of cases of tuberculosis have been most materially benefited. We should be doing great injustice to Dr. Dobell if we allowed it to be understood that he proposes his pancreatic emulsion as an infallible remedy in tuberculosis and phthisis, for he expressly states that many other conditions both of a hygienic and regimenic nature are to be observed in the treatment of this form of cachexia. Dr. Dobell, at the end of the book, reprints the different reports of his cases treated with pancreatic emulsion, together with summaries of the results.

The second of Dr. Dobell's books consists of a series of seven lectures upon cases of winter cough, occurring in the Royal Infirmary for Diseases of the Chest; together with an Appendix on some principles of Diet in Disease. The cases of winter cough are arranged by Dr. Dobell into five groups, namely: 1. Cases in which there are physical signs of emphysema and not of bronchitis, and in which there is no history of previous bronchitis. 2. Cases in which there are physical signs of emphysema and not of bronchitis, but in which there is a history of previous bronchitis. 3. Cases in which there are physical signs of bronchitis and not of emphysema. 4. Cases in which there are physical signs both of emphysema and bronchitis. And 5. Exceptional cases, in which there are not physical signs either of bronchitis or of emphysema. In the course of the lectures the conditions leading to emphysema and bronchitis are fully explained; and in the two lectures on treatment, all the therapeutic measures calculated to relieve these affections are fully explained. Dr. Dobell does not much approve of the use of atomized fluids for affections below the glottis, as they convey too great a quantity of cold and moisture into the air-passages, but this objection does not apply to fumes and vapours, which are among the most valuable means of acting upon the naso-pulmonary mucous membrane. The remarks on the other methods of treatment, whether climatic, medicinal, dietetic, or regimenic, are very judicious, and as a practical treatise on an extremely common class of diseases, Dr. Dobell's book deserves a high degree of commendation.

London Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 12, 1866.

THE CASE OF "DR." HUNTER.

THE result of the case HUNTER *v.* SHARPE, which occupied the attention of the Court of Queen's Bench for five days, will be received with considerable satisfaction by the public. It was an action brought by HUNTER, who is well known in consequence of his books and advertisements, against the *Pall-Mall Gazette*, for an alleged libel published in that paper, which denounced him as a quack and an impostor. We are sorry that the *Pall-Mall Gazette* should have been the victim of the late action, as that journal has always shown itself to be the consistent advocate of the just rights of the Medical Profession, and it was, in fact, in defending those rights that it exposed itself to the recent proceedings. It is also honourably distinguished by the exclusion of quack and indecent advertisements from its columns, and we should have been far better pleased if

one of the journals which have been reaping their thousands by the publication of the trash passing under the name of "Dr. Hunter's Letters on Consumption," had been made to suffer the annoyance and bear the expenses which have unfortunately fallen upon our meritorious contemporary.

As it is, "Dr." HUNTER reaps the barren honour of a verdict in his favour; but, as the damages are only *One Farthing*, he will have to pay his own costs, and, what is very much to be regretted, those of the defendants must be defrayed by themselves. Although, therefore, the moral effect of the verdict is the same as if it were given in favour of the defendants, yet the substantial loss of money on their part is, we fear, sufficiently great to deter them from following up their well-merited castigation of impudent and puffing pretenders, and from holding up to public obloquy many offenders far worse than "Dr." HUNTER. To the disgrace of our Press, the indecent announcements of the worst and most infamous of the gang who prey upon the fears of the weak and the credulous, are still permitted, in many instances, to pollute the columns of the newspapers, and the only change which some of the journals have made, in consequence of recent exposures, has been to increase the price of the advertisements, and thus actually to profit by their own infamy.

With regard to "Dr. HUNTER's Letters," although they do not belong to the category of indecent publications, their nature and tendency, which were long ago known to the Medical Profession, have now been thoroughly exposed in a Court of Law, and we can only refer to the admirable summing up of the LORD CHIEF JUSTICE for a true and correct indication of their real value. What defence the *Times* makes for its base and mercenary conduct in filling its columns, day after day, and week after week, with the contemptible farrago of folly and presumption, which many of the public believed, and which it was intended they should believe, were genuine contributions of a scientific character, we are at a loss to understand. To us the only possible defence appears to be that it was a money transaction; and if so, the reproach that PLUTUS reigns supreme over every consideration of honour and truth among the conductors of many of our public journals, will appear not altogether unmerited.

It appears that HUNTER's advertisements appeared in the *Times*, the *Standard*, the *Morning Post*, the *Daily Telegraph*, the *Star*, and the *Record*, besides many of the provincial papers. That most respectable journal, the *Daily Telegraph*, which is so indignant in its denunciations of all kinds of irregular practice, allowed it to appear no less than sixteen times, and our evangelical contemporary, the *Record*, gave thirty insertions to the same announcement, no doubt to the great edification of its readers. It was not, however, sufficiently indicated at the trial that these advertisements, which were of enormous length, and occupied whole columns, were so

published that they hardly looked like advertisements at all, but, even to the practiced eye, resembled scientific contributions put in by the editor, and they were therefore, in many instances, understood by multitudes of the public, as we can testify to our certain knowledge, as being *bona fide* contributions to the columns of the respective journals. Persons, therefore, who were ignorant of the power of money over our newspapers, actually believed that a new and successful method of treating consumption had been discovered, and, owing to the uncertain nature of our libel laws, no impartial and unbribed organ of the press dared to insinuate to the contrary.

We regret that the jury in the late trial should have returned a verdict for Dr. HUNTER, because we think that the defendant had proved his right to the verdict, and such was evidently the view entertained by the LORD CHIEF JUSTICE. The only conceivable reason why the plaintiff could be deemed entitled to a verdict was because the article in the *Pall-Mall Gazette* was supposed, on the theory put forward, to repeat or to assert the criminal charge brought against HUNTER by a Mrs. MERRICK at the end of last year. Now, in justice to the *Pall-Mall Gazette*, we do not believe that the article asserted anything of the kind; and, we must add, in justice to Dr. HUNTER, that we do not believe that he was guilty of the offence then imputed to him. But the criminal charge formed the vehicle by which the public were first made acquainted with the real nature of the advertising business carried on by HUNTER and his assistants, and the *Pall-Mall Gazette* took the opportunity, not of imputing to him the crime for which he was tried, but of exposing what it considered, and what we consider, as a course of conduct derogatory to the honour and dignity of the medical profession.

We are not at all surprised to find the *Times*, in a leader which appeared very shortly after the trial, treating the affair very lightly, and looking at Dr. HUNTER'S conduct as, on the whole, very excusable; but it is forced to admit, though in very guarded terms, that "the verdict (with a farthing damages) entirely meets the justice of the case, and that our contemporary (the *Pall-Mall Gazette*) is entitled to the thanks of the public for a courageous attempt to protect their interests."

CHOLERA.

FROM the returns of the Registrar-General, issued simultaneously with our last number, we extract the gratifying intelligence that only "three deaths from cholera were registered during the week ending on the 1st inst., and the epidemic is now virtually extinct." To this we may add that no death was registered until the following Wednesday, when one death took place.

During the whole time the epidemic has raged, there have been in the metropolitan districts 5548 deaths from the disease, exclusive of 2692 deaths from diarrhœa. In the epidemic of 1849, when the population of London

was about two millions and a quarter, 14,137 persons perished. In that of 1854, 17,738 died out of a population of two millions and a half. Thus the mortality of the disease has been less alarming this summer than in other outbreaks. Out of the 5548 deaths from the disease, 3909 took place in the Eastern districts.

The deaths to every 10,000 of population were 62, 43, and 18, in the three epidemics all over London. In the present epidemic the West districts lost 4, the North districts 6, the South districts 8, the Central districts 9; and it was only in the East districts, where the ravages recalled the violence of former epidemics, that 3909 people—that is, 64 in every 10,000 of the unhappy inhabitants—perished.

Holland and Belgium have published returns down to a recent date, for which the Registrar-General is indebted to M. de Baumhauer and M. Heuschling, and the facts prove that the epidemic is as fatal as it ever was under unfavourable sanitary conditions. Thus, in twenty-two cities and towns of Belgium and Holland, containing less than half the population of London, or 1,460,808 people, the deaths from cholera alone in the present year were 20,643. So the deaths were 141 in 10,000, and if the same proportion of inhabitants had perished in London, the deaths, instead of 5000, would have exceeded 42,000. In Brussels the deaths were in the proportion of 164, Utrecht 271, Amsterdam 42, in 10,000 inhabitants.

By the bulletin published monthly by the Prefect of the Seine it appears that the deaths from cholera in Paris were 6653 in 1865—that is, in the proportion of 39 to 10,000 inhabitants; while by the second outbreak in the present year 1812 persons had died by the end of July, the date of the last return, when the epidemic was increasing rapidly.

In London cholera has not only been less fatal than it was in previous epidemics, but its fatality has been reduced almost to insignificance in several of the districts by the mere force of hygienic science, before which the destroyer has retreated step by step; never, however, losing an opportunity of asserting its full power wherever negligence or ignorance presented an opening, either in England or in the cities of the Continent of Europe.

Cholera obeys certain laws, and the knowledge of those laws renders its subjugation in Europe practicable, provided all the people as well as the Governments will cooperate in the work. This it may be hoped will be done, and it only remains for the metropolis of this empire to hold its own and to keep the lead.

The annual rate of mortality in the week was 25 per 1000 in London, 30 in Edinburgh, and 31 in Dublin; 21 in Bristol, 25 in Birmingham, 31 in Liverpool, 28 in Manchester, 31 in Salford, 27 in Sheffield, 33 in Leeds, 26 in Hull, 39 in Newcastle-upon-Tyne, and 33 in Glasgow. The rate in Vienna was 29 per 1000 during the week ending the 17th instant, when the temperature was 2·6° Fahrenheit lower than in the same week in London, where the rate was 24 per 1000.

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29·822in. The barometrical reading increased from 29·34in. on Sunday to 30·15in. on Wednesday. The mean temperature of the air in the week was 38·7 deg., which is 2·7 deg. below the average of the same week in 50 years (as determined by Mr. Glaisher). The highest day temperature was 49·3

deg., on Tuesday. The lowest night temperature was 28.0 deg., on Saturday. The entire range of temperature in the week was, therefore, 21.3 deg. The mean of the highest temperatures of the water of the Thames was 42.2 deg.; that of the lowest was 39.5 deg. The difference between the mean dew-point temperature and air temperature was 5.0 deg. The mean degree of humidity of the air was 82, complete saturation being represented by 100. Rain fell to the amount of 0.02in. The direction of the wind was variable. According to a return furnished by the engineer of the Metropolitan Board of Works, the average daily quantity of sewage pumped into the river Thames at the southern outfall works, Crossness, was 162,706 cubic metres.

Notes on Current Topics.

THE OBSTETRICAL SOCIETY.

THIS day week, at an unusually crowded meeting of this Society, a paper was read by Dr. Tanner "On Excision of the Clitoris as a Cure for Hysteria." The subject was treated in a sensible and somewhat scientific manner, but unfortunately some of the speakers in the discussion which followed so far forgot what was due to their own reputation and to the Society as to indulge in unseemly and offensive personalities.

Whatever may be the conviction of any practitioner respecting the operation in question, we feel sure that the profession as a body cannot countenance such attacks as these upon the motives of an operator who has thrown open all his proceedings to their scrutiny, and makes it a rule to publish the results of his cases. But apart from this, some of the observations made were of such a character that we cannot possibly understand how the Chairman could permit them without interruption. We have on more than one occasion experienced the difficulties of presiding over so excited an assembly, but have felt it just to all peremptorily to put down such language as was indulged in at this meeting, and have accordingly insisted on our authority to do so. When sufficient time has elapsed to allow any disputants to cool, we have been cordially thanked for our firmness, and cannot but believe that the President of the Obstetric Society might have earned for himself the same reward. It is not our intention to enter upon the subject of the operation revived in these days by Mr. B. Brown. We only protest that in a professedly scientific assembly, not only that surgeons, but the whole profession, has a right to expect that opposition shall at least be subjected to the rules supposed to govern the conduct of *gentlemen*.

We sincerely desire to avoid unnecessary allusion to the topic, and we trust that now it has once been placed before a body so competent to guide professional opinion on such a subject, we may be relieved from the unpleasant duty of further comment. We look to the Obstetrical Society for an impartial verdict as the only atonement to be offered for the display of last Wednesday evening.

PROFESSOR TROUSSEAU.

In our last impression a paragraph, recording the death of this illustrious physician, taken from a contemporary, was accidentally placed under our heading of "Notes on

Current Topics." In making this *amende honorable* we have great pleasure in adding from another contemporary the following gratifying intelligence:—

"The reports concerning his death are unfounded, and the latest accounts from Paris state that his health is quite re-established."

DEATH OF DR. JEAFFRESON.

It is not without a feeling of intense regret that the profession will learn the decease of this widely-known physician. He died last Friday morning, the 7th inst., of typhus fever, from which, up to a late period, it was hoped he would recover. He was only 57 years of age, although, from the long period for which he has enjoyed the confidence of the profession and the public, not a few would have supposed him to have been considerably older. His M.D. Cantab. dates from 1838, and he was admitted a Fellow of the London College of Physicians in 1839. He commenced his professional career in Finsbury-square, where he continued to practise until a few days since. At an early age he obtained an appointment on the staff of St. Bartholomew's Hospital, to which he has been for some years full physician. Dr. Jeaffreson confined himself strictly to the practice of his profession; he neither wrote in the journals, published monographs, nor indulged in other literary or scientific distractions; yet we may venture to say that no physician in the City enjoyed a more extensive consulting practice, nor was any name more frequently mentioned with respect and confidence by his professional brethren and the public at large. From the commencement a successful man, he so combined the qualities of the courteous gentleman with those of the well-informed physician, that those who remember him will freely acknowledge that he set them an example well worthy of imitation.

SANITARY STATE OF LIVERPOOL.

MR. ALFRED TAYLOR, C.E., who recently held a Government inquiry into the sanitary state of Liverpool, has just presented his report. This only corroborates the remarks we have frequently been called upon to make on this subject. Mr. Taylor recognises the necessity of considerable improvements, and wisely advises the conversion of all privies into water-closets, and a much larger supply of water, so that the sewers may be properly flushed. He also recommends the establishment of suburban manure wharves to replace those in the city. His recommendations are of the utmost importance, although they can scarcely be said to exhaust the subject.

YELLOW FEVER AND QUARANTINE.

THREE vessels which have arrived in Southampton Water have now been subjected to quarantine, on account of yellow fever. We do not deny that the cases of the *Tyne* and the *Seine* have been much better managed than that of the *Atrato*, which was unfortunate enough to be the first ship on which the Privy Council imposed restrictions. In the two latter cases the sick have been removed to one ship, and the healthy to another, and a desire has been manifested to make the burden of detention as light as possible. There is, however, much to be done, and if quarantine is to be established on our coasts, no expense ought to be spared to protect and comfort the unhappy sufferers by it. It would seem after the blunders that

have been made, and the unsatisfactory conclusions of the international conference, that the present would be a good opportunity to make a complete inquiry into the whole subject of quarantine.

INDIAN MEDICAL SERVICE.

We understand the arrangements have at length been completed for the new Army Staff in India—viz.: For Bengal, 1 inspector-general of hospitals, 6 deputy inspectors-general, and 2 staff-surgeons-major; for Madras, 1 inspector-general of hospitals, 3 deputy inspectors-general, and 1 staff surgeon-major; for Bombay, 1 inspector-general of hospitals, 3 deputy inspectors-general, and 1 staff surgeon-major. The rates of pay will be as follow:—Inspector-general in Bengal, 2700 rupees per month; in Madras and Bombay, 2500 rupees per month. The deputy inspectors-general will each receive 1800 rupees, and staff surgeons-major 1400 rupees per month. There will be also secretaries and statistical officers appointed to the three stations, at 700 rupees the former, and 600 rupees the latter, per month.

BREATHING SPACE FOR PAUPERS.

At the last meeting of the Vestry of Lambeth, as we learn by the *South London Chronicle*, an important statement relative to the mortality in the workhouse was made by the Medical Officer of Health, Dr. Puckle. In one of the wards, containing no fewer than eighteen persons, there was a case of infectious disease, and in that ward there were not 300 cubic feet of space. Seven deaths have occurred within a fortnight. The explanation of the doctor is that the death-rate is enhanced by the overcrowding of the wards.

GRATUITIES TO PUBLIC VACCINATORS.

It is rumoured that Government is about to institute a system of gratuities to public vaccinators, according to the degree of success, and that a sum of money has been provided for that purpose. It is known that such a plan was proposed in the bill which was settled by the Select Committee of the House of Commons last session, but with which, as our readers are aware, the present Ministry did not proceed. We have reason to believe that the present rumour is well founded.—*British Med. Jour.*

We understand that it is intended that a deputation from the Royal College of Surgeons in Ireland will shortly wait on the Chief Secretary for Ireland, with respect to the admission of Medical Officers to the Irish Poor-law Service at a lower age than that at present required.

METEOROLOGY OF NOVEMBER, 1866.

MR. R. H. ALLNATT, whose observations we have previously published, has issued an account of the weather during the past month, from which we make the following selection:—

The past month will be memorable in the future annals of meteorology. Its epoch of revolving meteors has been marked by such a display as was probably never before witnessed in England. It was also characterised by destructive gales, disastrous floods, and other signs of violent atmospheric perturbation:—

ANALYSIS.

Cloud.—The cloud modifications of the month were varied and often of exceeding beauty. At sunset bright vermillion cumulus and purple cirro stratus frequently co-existed in

deep contrast, and streams of radiant cirrus were projected over the face of the hemisphere, from horizon to horizon. On the 16th a storm passing over the sea produced a succession of solar rainbows. The predominant form was the cirro cumulo stratus, composite, or true rain-cloud, in homogeneous combination or isolated in their respective strata.

Wind.—On the 7th a destructive gale, amounting to a hurricane, visited Leith, on the Scottish coast; its focus bearing directly upon the railway station, with a force almost incredible; the roof, 100 feet long and 30 feet broad, was borne 20 feet high in the air and was carried over some high houses, when it struck a chimney-stalk, which it brought down from its foundation with a tremendous crash, without being arrested in its progress. It then descended upon the telegraph wires, which, of course, it demolished. On the 14th a gale raged in the Baltic and German Ocean. On the 16th the seaports at Shields were in a state of great excitement, as a violent gale and fearful sea were raging which drove several vessels on shore, and gave occupation to the lifeboats. On the 17th a severe gale blew from N.E., and struck the coast of Great Yarmouth. It was accompanied by showers of sleet and snow. In the midst of a very heavy sea two ships were driven ashore, became total wrecks, and their crews drowned. At Shields, on the same date, an easterly gale raged with such fury that a vessel was driven on a reef of rocks S. of the Tyne and lost. The crew were enabled to jump from the jib-boom on to the rock without the assistance of the lifeboat. On the 18th another severe gale broke over the S.W. coasts, attended with heavy rainfall; and as I now write, on the evening of the last day of the month, a gale which has lasted the whole day, from S.E. is subsiding with the ebbing tide.

Barometer.—The extent of the diurnal barometric oscillations was considerable, and during the continuance of the wet and tempestuous weather which prevailed the height maintained by the barometer was extraordinary. On the 16th, a few hours preceding the transient gale which rose in the evening, the barometer sank upwards of half an inch, and the following morning as suddenly rebounded 6-10ths—that is to say, from 29.40 to 30.00 in. Again on the 17th it rose in the evening to 30.00, and before nightfall sank nearly 3-10ths.

Thermometer.—The first frost of the season occurred in Yorkshire on the night of the 10th, when the annuals and other garden produce, which had hitherto been unscathed by cold winds, were blackened and destroyed. Thermometers in Scotland, Ireland, and Wales, and on the various coasts of England on the same date indicated several degrees above freezing, although it was the coldest night hitherto of the month. At Valentia the temperature is quoted at 56 deg., which is probably either an error of observation or record. On the 20th and 21st the night readings were 29 deg. Fahrenheit, 3 deg. below freezing point. These were the only frosts of the month.

Rainfall.—The rainfall of the month has been most unequally distributed, several counties having been merely visited by their normal quantity, while others have been deluged by successive rains. In Yorkshire, Lancashire, and Derbyshire the quantity has been enormous. The Irwell, the Irk, and the Medlock burst their boundaries and rushed through Manchester as roaring cataracts, bearing huge bulks of uprooted trees and an indescribable *melee* of wreck. The inundations swept over villages, rolled into cellars, and invaded warehouses and human habitations up to the second story, drowned horses and cattle, and extinguished furnaces, stopped trains at full speed, choked tunnels, submerged immense sweeps of field and pasture so deeply that hedges disappeared and swept away many human beings. Boats navigated the streets of Wakefield, and waggons were engaged in rescuing people imprisoned in their houses by this fatal deluge. In Avenham-park the tops of lofty trees were alone visible, and the valley of the Calder for five miles became an unbroken lake, At Leeds a most serious and tragic event occurred; the victims were crowded upon a wooden terrace overlooking the rising stream, when it suddenly became undermined by the eddying waters, and, giving way, they were plunged into the current. Six women were dragged out grasping each other in a desperate embrace, some were dead, and others were hurried down by the increasing tide to be stranded when the fury of the tide should cease. An enormous amount of property has been swept away; railways impaired; the complex and delicate machinery of hundreds of mills has

sustained irreparable injury; quays and wharves have been inundated, and their stores of wealth and industry swept away. The gross amount of damage is estimated at half a million sterling. The precise quantity of these northern rainfalls has not yet been ascertained, but it will materially influence the aggregate average of the month.

Ozone.—Very moderately developed. On the 4th, 11th, and 13th the registry was a unit only, and the 12th was a period of antozone.

Meteors.—The magnificent and protracted display on the night of the 14th will, it is confidently believed, afford tangible data to meteorologists for determining the physical properties of these mysterious bodies. We yet await authentic reports from the more remote regions of the world.

MEDICAL TRIAL.

HUNTER v. SHARP.

WE regret that want of space precludes the possibility of our giving this case in full; we, however, give the following summing up of the Lord Chief Justice:—

The Lord Chief Justice, in summing up, said—That this was an important case there could be no doubt; it was important to the plaintiff unquestionably, because upon their verdict would depend his professional position, his fortune, success, and, what was of more importance, his personal character in society; for if he was convicted of being an impostor his personal character would be irretrievably ruined. The case was also of importance, because it involved more or less the principle by which the conduct of a public writer and his responsibility for what he wrote was concerned. It was also important because incidentally they might have to consider how far the character and dignity of an honourable profession might be sullied and tarnished by recourse being had to a course of puffing by advertising to which the plaintiff had thought fit to resort. There were one or two preliminary matters which might as well be disposed of before they came to the real matter in issue. In the first place, there could be no doubt that unless it could be justified on the score of its truth, or excused as privileged, the article was libellous. To say that a man was an impostor—that he first frightened people into becoming his patients, and then treated them by pretended remedies, and that he did all this for the sordid purpose of putting money into his pockets, was unquestionably matter of a very serious and libellous character. Again, there could be no doubt but that the article was directed against the plaintiff. He was named by name, the unfortunate circumstance of a charge having been brought against him by Mrs. Merrick in the police court was referred to, his double diploma was remarked upon, and no reasonable man could doubt that the plaintiff was the person to whom the article intended to refer. Indeed, no attempt had been made on the part of the defendant to disguise that fact from the jury. Lastly, the defendant was unquestionably liable to this action. The defence was rested upon two grounds. In the first place, the defendant said, "What I have written and published is true; and as by the law of England truth is not libellous, I am justified in writing the article complained of." In the second place, he said—and it was a matter well worthy of their consideration—"Even if I should fail in making out to the necessary extent the plea of justification—in other words, the truth of the libel—nevertheless, I say that, looking at all the circumstances of the case, I, having exercised all needful caution in the matter, having exercised my judgment to the best of my ability in discussing a subject concerning the public, was justified in writing the article in question." He would proceed to deal with those questions in the order in which he had referred to them. In the first case came the question whether the defendant had established his plea of justification—in other words, whether they were satisfied that the facts set forth, however damaging to the plaintiff's character, were true; and in order to arrive at a decision upon this point it was quite obvious that they must look very critically at the book which the plaintiff published. But before they turned to that work he would shortly refer to the charge contained in the alleged libel. Having carefully considered what the charge was they would be enabled to see how far the contents of the plaintiff's work and of his advertisements justified it. Now the charge was

that the plaintiff, in dealing with one of the most fearful diseases to which the human frame is subject, with the intention of obtaining profit and gain to himself, began by exciting, unnecessarily, the fears of those who might read his publication, and then proceeded to hold himself out as the only person who could cure them effectually—that he induced them to trust in the remedies which he prescribed, which he knew to be delusive, and that thus he tampered with their health and trifled with their hopes, for the sordid purpose of putting money into his pocket. If the charges were true, hardly anything could be worse than the conduct of the plaintiff. The language used in the article was of the strongest and most bitter character; but if the facts upon which the article was assumed to be grounded were true—if it were true that the plaintiff had intentionally, fraudulently, and dishonestly put forward such statements as were contained in his book in order to make those who read that work his victims in purse, if not in person, no language could be too strong in which to describe his conduct, for he would not only be an impostor, but an impostor and a swindler of the very worst description. Of course it was obvious that the more serious such a charge, if well founded, would be, so much more would a person against whom an unfounded accusation of the same was made be entitled to look at the hands of a jury of his countrymen for ample and proportionate redress. Bearing in mind what the charge was, let them look at what the plaintiff had done. He must, in the first place, draw the attention of the jury to one or two parts of the alleged libel, as to which it was contended the defendant, having offered no justification, as he had tendered no evidence with respect to them, the plaintiff was entitled to their verdict. That must greatly depend upon the construction which they put upon those passages relating to the proceedings in the police court in Mrs. Merrick's case. Now did they believe that in writing those passages the author of the article intended to convey that Dr. Hunter was guilty of the offence with which Mrs. Merrick charged him? Because in that case the defendant having offered no evidence on that point, the plea of justification utterly failed, and their verdict must be for the plaintiff upon that plea; or on the other hand, did they believe that the charge at the police court had only been made use of as the occasion, and was not the substance of the article against the plaintiff? These points, however, although they might enable the plaintiff to obtain a verdict, were not the real matters of contest between the parties. The plaintiff had been acquitted by the verdict of a jury of Mrs. Merrick's charge, and therefore the article in question could not injure him, in that respect, although it was doubtless published at a most inopportune moment, namely, when the charge was still hanging over the plaintiff's head. The main question between the parties was this: was the system which Dr. Hunter had propounded one which an honest medical writer and practitioner would have put forward? Was it put forward for the mere purpose of enlightening the profession and the public as to his system of cure; or was it a system of quackery which he promulgated for the sordid purpose of putting money into his pocket? The plaintiff came forward professing to understand as others had not understood the true cure of consumption; he came forward professing that whereas the whole medical profession had abandoned the hope of curing this terrible disease, he had discovered means whereby in its incipient stage certain cure could be effected, while even in its more advanced stages the patient who submitted to his system might be restored to health. By way of introducing his mode of treatment, and in order to show that it must be efficacious, the plaintiff in his book entered into an account of what were the causes of this fatal disease. He said it had been the fashion hitherto to believe that consumption, or, in other words tubercles in the lungs, was the consequence of an hereditary predisposition to disease. That, he said, was a fallacy. The true and only cause of it was impaired respiration. The plaintiff said that carbon was tubercle, and tubercle was carbon, and how were you to remedy the disease set up by the obstruction of the organs of respiration? The only mode of remedying the disease was to introduce oxygen by artificial means. He said he had discovered a preventive, or rather that he possessed an instrument whereby oxygen could be inhaled or artificially conveyed into the lungs. He further said that the medical profession knew nothing of his system—that they treated the disease by medicines administered through the stomach; that it was all idle and de-

lusive, because medicine taken through the stomach could not reach the part locally affected. The oxygen operated with two-fold effect. In the first place it acted immediately upon the carbonaceous matter of the tubercle which it decomposed, whereby the lung healed; and in the second place it entered into the system by oxidising the blood, which was thus enabled to restore healthy matter in place of the worn out tissues of the body. If the plaintiff's theory were true, no greater blessing could have befallen mankind than the discovery of which the plaintiff boasts himself the author. But they were told, and upon high scientific authority, that the whole of this supposed discovery was purely delusive; in the first place that it was not true that imperfect respiration was the cause of tubercles in the lungs, and that the assumption of what appeared to be the foundation of his system was wholly delusive, since it required either hereditary taint or circumstances which conduced to a scrofulous disposition in order to produce consumption. They said further that the plaintiff was deluding himself or the public when he said that tubercle was carbon, or at all events was carbon united with worn out tissues, and that it was those two assumptions which proved the basis of the plaintiff's whole system, both as regarded the disease and the means of treating it. Then came the question whether tubercle was, as he described it, composed of carbon. The defendant's witnesses said that it was certainly untrue, and they said that the authority upon which he based that assumption, namely, Scherer's analysis, was misunderstood, or more properly speaking, misrepresented by the plaintiff, as to tubercle containing more carbon than the other animal tissues. They said that had he been an ordinary intelligent medical man he must have known that what he was writing was untrue. They said that even assuming that he was right in his assumption that the principal element of tubercle was carbon, and that the introduction of oxygen by purifying the blood, or by decomposing the carbonaceous deposit, when they came to the practical treatment proposed by the plaintiff, they would find it to be utterly untenable either in theory or in practice. In the first place oxygen could only be introduced into the system to a limited extent, because the act of inhalation was exhausting to the patient, and could only be carried on for a limited period. Considering the enormous quantity of oxygen that was inhaled by ordinary respiration, they were told by the medical profession that the quantity of oxygen that could be inhaled by artificial means would be so infinitesimally small that it would be of no effect, that it would not be more than 1 per cent. Therefore the medical profession said that that part of Dr. Hunter's theory was a delusion also, and further than this they said that even if they could get the oxygen into the lungs it would not be beneficial. Then it was shown that oxygen could only be obtained in combination with other bodies, and that it is evolved by the use of chloric acid, as stated by Dr. Hunter, both oxygen and chloric gas were produced, the latter of which was most irritating to the lungs of the patient. He did not know which three of the gentlemen of the jury—for that was the proportion, according to the doctrine of Dr. Hunter, which should be affected with incipient or actual consumption—were in that unfortunate state (laughter); but he was sure they must be most interested in this discussion. However, it was not because a man put forward erroneous notions in any science that he was to be held up to universal scorn. When a man puts forward views of any kind on a matter of public concern he challenged criticism, and the man who differed from them was justified in criticising them with severity, and might even hold up his views to ridicule, although he had no right to impute sinister motives to him. It was not, therefore, because scientific men had satisfied them that the views of the plaintiff were erroneous that he was to be held up to society as an impostor, a swindler, and a scoundrel. In order to ascertain the motives of the plaintiff in publishing his work they must look a little closer into the contents of his book. In the first place, what were the charges? It was said by the defendant that the plaintiff had put forward his theory for the purpose of frightening timid persons to become his patients, in order to gain pecuniarily by them. The plaintiff's book warned those who were afflicted with these complaints that if they resorted to their ordinary medical attendants for advice, although they might apparently improve in health, they were the certain victims of consumption. On the other hand the medical profession said that such statements were utterly false. If they thought

that these statements were put forward by the plaintiff with a knowledge that they were untrue, and with the sinister design of putting money into his pocket, they must say whether they were of opinion the article in which the plaintiff was described as a swindler and an impostor went one whit beyond what the circumstances justified. There were two or three passages in the plaintiff's book which were very important indeed, as enabling them to arrive at an accurate judgment as to the honesty or dishonesty of the plaintiff in publishing that work. Thus, in one part of the work he stated that a common cold in the head would, if not checked, tend to the loss of the bones of the nose (laughter). This was at least rather a startling proposition. Then he proceeded to remark how a sore throat must lead to consumption, unless it was immediately cured, adding that patients having such a complaint would soon find how short a step led from a sore throat to consumption if he remained under the hands of his ordinary medical adviser. It was also rather startling to hear that the tickling in the throat arising from an elongated uvula might be the precursor of speedy decline. It was for the jury to say whether they thought that the experience of the medical men who had given their evidence before them in the witness-box were to be received as truth rather than the statements contained in the plaintiff's book. It was also for them to say whether they believed those statements on the part of the plaintiff to have been put forward as the result of honest conviction of their truth, or merely for the purpose of deceiving people into believing that they were in danger of losing their lives. In all cases where it was suggested that a man had done a dishonest act it was incumbent upon them to see whether he was interested in the result, and whether he had made his profit a prominent feature. Now the plaintiff alleged in his work that medical men, although they tampered with the disease, by administering cod-liver oil and other nauseous mixtures, had abandoned the idea of effecting a cure, whereas he alone had discovered a certain remedy for the disease, and, therefore, if they wished to be cured they must come to him, as he alone could and would cure them. Another point that must be considered in coming to a determination as to the good faith of the plaintiff was, that he described as unmistakable symptoms of consumption such things as shortness of breath on walking up a hill—an affliction from which every person in years suffered (laughter), or an acceleration of the pulse, which might be the result of a slight cold. Again he said that losing flesh was a sign of consumption, although he added that this was not a necessary consequence of that disease, as it frequently happened that plump, pretty, rosy-cheeked girls, looking the very picture of health, were marked as the victims of consumption (laughter). It was for the jury to say whether these statements were put forward by the plaintiff for the honest purpose of enlightening the profession or the public, or for the more sinister motive which was alleged in the article complained of. Undoubtedly the tenor of the book was to show that it was useless to go to the ordinary practitioner for advice as to the treatment of consumption or its premonitory symptoms. It mattered not what confidence might be placed in the medical man, or what honours he had achieved in his profession, if there was anything the matter with the respiratory organs, he was unfit to remedy the evil, and the patient must necessarily turn—to whom? Why, to the man who administered medicines by means of inhalation, and did not give his patients cod liver oil. And who was that? Why, the plaintiff, who was possessed of the necessary instruments, and of the requisite knowledge for curing the complaint by his peculiar mode of treatment. He was most anxious not to draw any deduction from the book which was not justified by its contents; but was it possible to read it without coming to such a conclusion as he had suggested? They must, however, take care that a man should not be held up to the finger of scorn simply because he had put forward a theory which, upon being strictly tested by the rules of science, was found erroneous. It might be that when a valuable discovery was first brought to light the profession, who were told that all their preconceived ideas were worthless and their learning useless, might object to the introduction into practice of the new theory, that they might say the theory had no substantial foundation, and might stigmatize its author as an impostor and a quack, and it would be the duty of the jury to take care that a man was not crushed and driven out of the profession for such a reason. On the other hand they knew by the history of the

world that from the earliest ages men had sought to impose upon the credulous by acting upon the fears of mankind, by pretending to be possessed of the power of healing all the ailments and diseases to which human nature was subject, men who had trifled with the misery and suffering of their fellow-creatures for the purposes of their own sordid interests. The denouncement of such pretenders was, perhaps, one of the most meritorious actions in which a public writer could exercise his power. It might certainly be that the plaintiff, while he made dupes of others, was himself a dupe of his own theory. He might believe that he had hit upon a great discovery, by which he believed he could cure this fatal disease; but it might also happen that his knowledge as a medical man had shown him that the best way of acting upon mankind was by working upon the fears of the timid and nervous, by leading them to believe that they were marked as the victims of a disease which he alone could cure. Nor must they confine their attention to the book alone; they must also look at the circumstances under which it was published, and of the method of advertising which had been adopted by the plaintiff. The medical man who had been examined had told them that the plaintiff's book was deficient in one essential particular—a particular by which a genuine work, published by a scientific man, was distinguished from that of a quack—namely, that it did not contain in distinct and clear terms the method of cure adopted by the plaintiff. The object of a scientific medical man in publishing a work was to enlighten the members of his profession, and enable them to treat patients according to his method, whereas the object of the quack was to conceal his method, and thus to keep his system of cure a secret for the purpose of making money by its means. They had been told that in this respect the work was altogether silent, and that no medical man could by reading the work in question apply the plaintiff's system to his patients. But this book was said to have passed through edition after edition with unexampled rapidity, and he could scarcely see the necessity for publishing the advertisement respecting it even in the *Times*—since if it passed through fifty-six ordinary editions in a month every man, woman, and child in the kingdom must have been engaged in reading the work. Could it be supposed that these were ordinary editions? Again, there were prefaces to the work purporting to be written by two physicians, who turned out to be merely assistants to the plaintiff. Would it not have been as well if the plaintiff had made that fact public instead of leading people to believe that two gentlemen high in the profession had stamped the work before it came out with their unqualified approval? But would any medical man in England, if ever he published a treatise upon any branch of his science, resort to the quack-like expedient of advertising himself in the way the plaintiff had done? The plaintiff, however, was not satisfied with the repeated and successive editions of his work. He had resorted to the extraordinary and unprecedented expedient of taking his book to pieces, and of publishing it by instalments in the daily papers. Had he employed a hundred criers to hawk about his book, or had he stuck up large placards at every corner in the streets, he could not have resorted to a better means of making his book known than by the course he had adopted of publishing it by portions of a column at a time in the various newspapers. Even the learned counsel who appeared for the plaintiff could not in any way approve of this course of proceeding, and endeavoured to excuse it, by stating that the plaintiff came from America, where advertising to any extent was legitimate. But they were not in America—they were in England, and whatever might be the practice in the former country, he was happy to say that such a practice had not extended to this kingdom. The rule here was this—that quacks advertised, but professional men did not; and no one could doubt that if it were open to medical men to advertise their attainments, the honour and the dignity, and the respectability of the profession would soon become tarnished and soiled. What would be thought if a member of the Bar in publishing one of those treatises by which from time to time they were enlightened and instructed were to take portions of it, and publish it day after day as an advertisement, taking care to append to the advertisement the important piece of information that he would sit daily at his chambers, from ten to six, to advise with clients who came to consult with him (laughter)? Such an individual so acting would be scouted from the profession which he disgraced. Then why

should such a system be permitted in the sister profession the honour of which was equally dear to its members? Therefore, until he had some better evidence to the contrary, he did not and would not believe that any such practice was resorted to by the medical men in America. The plaintiff had undoubtedly brought forward a number of witnesses who alleged that they had been cured by his method of treatment; but of the twelve who so came forward, only two were alleged to be cases of consumption, and even of those two only one had been informed by an independent practitioner that he was suffering from consumption—an assumption in which he might have been mistaken. A gentleman in Canada had declared that he had been materially benefited by the plaintiff's system, but in that case, as in that of the Polish Countess, there was no reliable evidence before them to establish the fact that those persons were really suffering from that disease when treated by the plaintiff. Supposing that the defendant had failed in showing that the plaintiff was an impostor, he might still rely upon his second ground of defence, which was that, as a public writer, he was justified in writing the article in question, as an honest and fair comment upon a matter of public concern, even although it might afterwards turn out that the assumed facts upon which the article was founded were not correct. He fully endorsed the proposition that if a public writer in commenting upon a matter of public concern exercised honestly his powers of criticism, he would be justified in so doing, even although the facts might fall short of what he had supposed them to be. The occasion in such a case was a privileged one, and he was entitled to the protection of his privilege. It was undoubted that the article was written in a spirit of extreme bitterness and of extreme severity, which could only be justified by the assumption that it was written by a medical man who was defending his profession from what he regarded as a stain upon its honour and its dignity. The whole matter was, however, one for the determination of the jury. They must weigh the whole of the circumstances that had been laid before them in the course of this lengthened trial, and must say—first, whether the libel was true; secondly, whether it was a fair comment, honestly written upon a matter of public concern; and if they found both those questions in favour of the plaintiff, to what amount of damages he was entitled.

The Jury retired at twenty-five minutes past twelve o'clock, and on returning at half-past two o'clock,

The Foreman said they found a verdict for the plaintiff—damages, one farthing.

The Lord Chief Justice—I wish to know whether it is your opinion as a matter of fact that the article was intended to convey that the imputation with regard to the offence alleged by Mrs. Merrick to have been committed was true?

The Foreman—We have taken the article as a whole.

The Lord Chief Justice—Then you consider that the justification was not entirely made out?

The Foreman—Yes, my lord, we do.

The verdict was then entered for the plaintiff for a farthing damages.

Correspondence.

MR. RICHARDSON'S REPLY TO MR. P. C. SMYLY.

PERREVE'S STRICTURE DILATOR.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

STR.—Had your correspondent, Mr. Philip C. Smyly, been courteous enough to have spoken to me on the subject of his letter before he rushed into print, I think I could have satisfied him that I was not guilty of any "mis-statement," nor of any injustice to Mr. Holt, and thus he would have been saved the unpleasantness of being himself detected in error, on the very point upon which he assumes to be an authority.

Your correspondent has not cited a single authority to sustain his charge. It rests on his own unsupported assertion. This might do very well in a matter of opinion; but, the question at issue is about a matter of fact—namely

whether the instrument I alluded to in my communication of the 7th of last month, is the invention of M. Perrève or of Mr. Holt.

Your correspondent himself nearly decides this point, by the admission that Mr. Holt confesses—(but more of this by-and-by)—that he took the idea from M. Perrève's instrument, which is quite corroborative of my position.

I now deliberately affirm that the instrument generally known under the name of Holt's is, for all practical intents and purposes, a counterpart of that of M. Perrève, being almost identical with it in form and action. And I shall, in a few moments, proceed to give the authority, as well as the proofs, for this statement, which will show the injustice of the attempt to despoil M. Perrève of whatever honor belongs to the invention.

Before I do so, however, and in order that your readers may have the whole matter before them, I shall here reproduce your correspondent's letter from your number of the 21st last month:—

"HOLT'S INSTRUMENT.

"TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

"DEAR SIR,—I hope you will do me the favour of correcting a mis-statement made by Mr. B. W. Richardson. Mr. Holt's instrument is his own, and not Perrève's. If they are the same instrument, why should Mr. Holt's be generally adopted by the profession, at least by most of the first practitioners both in England and this country, while Perrève's, which has been known for many years previously, has been completely rejected? The idea, Mr. Holt himself acknowledges, he derived from Perrève's. The practical and useful, I might say invaluable instrument, now so generally used, the profession owes entirely to Mr. Holt.—Yours sincerely,

"PHILIP C. SMYLY."

I shall first give the authority for my assertion, and then prove my accuracy in attributing to M. Perrève the invention of the instrument known by the name of Holt's.

In the fourth volume of Holmes' excellent "System of Surgery," there is an article on the "Diseases of the Urinary Organs," from the pen of a gentleman who holds the highest place as an authority upon any question concerning the diseases and surgery of these organs. Need I mention Mr. Henry Thompson?

In that part of Mr. Thompson's invaluable contribution, where he speaks of the mechanical apparatus for dilating stricture, he writes as follows:—

"The attempt has been frequently made to dilate a stricture by means of a single instrument, which expands *in situ*, in the place of several instruments of increasing calibres which require to be successively pushed through the constricted part. With this object, Mr. Luxmoor (1812) employed diverging metal rods; Leroy d'Etiolles the same method some years later; and M. Perrève a somewhat similar plan (1847). Dr. Arnott commenced the employment of fluid expansion (1819). More recently Mr. Holt has adopted the method of forcible rupture by means of an instrument *precisely similar to that of Perrève*, and has operated many times with success, and a greater freedom from serious consequences than would generally have been supposed, since he ruptures the strictures with considerable force."

Dates are of some importance here, the fourth volume of Mr. Holmes' work having appeared in 1864. Notwithstanding, Mr. Holt himself, as far as I am aware, has allowed the above statement (which I have marked in italics) to remain uncontradicted, unless we are to assume that your correspondent's letter was written by the authority, and under the supervision of that gentleman, which, however, its construction and reasoning does not justify us in so doing.

Mr. Thompson's name alone is a guarantee that no injustice could have been done to Mr. Holt in this matter; and I shall, in a few moments, demonstrate that, with the exception of the conducting rod being hollow, instead of solid, he was most accurate in stating that Mr. Holt "has adopted the method of forcible rupture by means of an instrument *precisely similar to that of Perrève*." But, for all practical purposes, and in all the essentials, I repeat, the two instruments are identical in form and action, so much so, that the instrument used by Mr. Holt is evidently a reproduction of that of M. Perrève.

There can be no better proof of this position, than the description by Perrève, himself, of his ingenious dilator.

Victor Perrève's *Traité des Rétrécissements organiques de L'Urètre*, which I have now before me, was published so far

back as 1847; and, although your correspondent is familiar with the name of the author of the work, he is evidently unaware of its contents, as the following passages and illustrations from the volume itself will show:—

"THE NEW DILATOR.

"This instrument has a length which exceeds that of the urethra. Its volume varies, as its name indicates; but it is no more than the manner of sounds or bougies which increase in size, in proportion as we recede from their vesical extremity; the augmentation in volume of my dilator is not inherent in the material; for, it is uniform in all its length; it depends on opposed movements, which separate from, and approximate to, the central part, the moveable pieces which compose it: it is, if you wish, a cylindrical sound, which we can, at will, augment or diminish in volume in all points of its length; it is also, if you will, an expanding sound. This preliminary stated, let us pass to the detailed description of the instrument: and to avoid all confusion in language and ideas, we will at first describe it under the curved form, after which we will examine it under the straight form.

"CURVED DILATOR.

"The curved dilator is composed of:—
 "1st. Two curved urethral blades or shafts;
 "2nd. A conductor;
 "3rd. A hollow mandrel (forcer);
 "4th. Two clamps.

"FORCER, OR CONICAL WEDGE.

"(A.) *Urethral blades*.—The urethral blades are ten inches in length; each of them represents, for an extent of eight inches and a half, a half cylinder cut according to the direction of its length. Their convex surface is perfectly polished, and having the divisions of the foot. Their plane surface, whose lateral angles are rounded with care, has along its middle part a longitudinal groove or gutter, destined to lodge the conductor. Towards the part of the instrument which corresponds to the broad end of sounds, each shaft or blade presents laterally four notches for receiving the uprights of the two little clamps. The lateral notches of the upper blade prevent drawing of the shafts when we pass the forcer between them.

"(B.) *Clamps*.—The two clamps (Fig. c c. 1 and c c. Fig. 4) circumscribe each a rectangular aperture, the width and height of which are such that they can contain at the same time, but without allowing of too much play, both the blades and the largest of the forcers which the instrument is required to receive."

The reader's attention is particularly requested to the words printed in italics, inasmuch as they show that Perrève was fully alive to the danger of the upper blade being permitted to have a lateral play when the forcer is being pushed home. Precaution against this lateral motion of the upper shaft is considered to be a feature peculiar to the instrument used by Mr. Holt. Let us proceed:—

"One of them (*clamps*) is deeper than the other; and this excess of length is destined to serve as a point of resistance, when we wish to push the forcer between the shafts, to produce the action of the instrument. One of the uprights of each clamp has a small projection pierced with a tapped hole for receiving the screw.

"(C.) *Conductor*.—The conductor is a wire of English steel, untempered, the length of which is from twelve to thirteen inches, and whose diameter should not exceed two millimètres."

Fig. 1.

* A. curved dilator, with forcer *in situ* on conductor, a little under half real length. Traced from Perrève's original plate, and engraved by William Oldham. b. Separate wedge or forcer. c c. Clamps. d. Conductor.

A conducting rod has been said to be Mr. Holt's addition to the dilator.

"(D.) *Forcer*.—(Fig. 1. b.) The forcer is a tube of eight inches in length; its exterior diameter should not exceed two lines. The canal, with which it is pierced its whole length, should have a diameter such, that it permits the free passage of the conductor. One of its extremities has a button handle, upon which is engraved its number of size or order, while the opposite extremity is conical. In half of its length, that which corresponds to the handle, it presents a series of small slits, separated, the one from the other, by intervals which should not have more than a line of extent."

"(E.) *Curette*.—As accessory, and useful, we shall add the curette. It is a small metallic rod; its length slightly exceeds that of the forcer, and its diameter equals the diameter of the canal with which the forcer is pierced throughout its whole length. *Uses*.—The curette, passed occasionally

into the interior of the forcer, serves to clear the latter of the coagulated blood which obstructs, or may even completely prevent, the free entry of the conductor.

"It is manifest that, if we cause the forcer to glide upon the conductor, and push it between the shafts, these separate from each other and thus augment the volume of the instrument."

When the diameter of the dilator is small, Perrève expressly states "that it would be imprudent to unite the vesical extremity of each blade by means of a hook and mortise," as in his large models;—"this means of articulation would want the solidity which should always preside over the construction of instruments destined to enter the urethra; thus the blades of the dilators which are less than two lines in diameter are, towards their vesical extremity, soldered together with copper or with silver, in the extent of about two or three lines." (Figs. 1, 2, and 4.)

"STRAIGHT DILATOR"

Fig. 2.*

"With exception of the curve, the straight dilator resembles, in every way, the curved dilators, which have a line to a line and a half in diameter. In effect, the straight dilator (Fig. 2) has two clamps, a conductor, two urethral blades, soldered at their vesicle extremity, and, like all curved dilators, its expansion or development is made by means of a forcer."

Perrève used the straight dilator for very narrow strictures, in order to free a passage for his larger curved instruments.

They appear to me very suitable for strictures in the anterior portion of the male urethra: and also for the female urethra.

"FORCERS—THEIR NUMBER; THEIR DIAMETER."

"Three forcers suffice for the use of all the dilators. The following is the order of size of these forcers:

"No. 1. A line in diameter."

"No. 2. A line and a half in diameter."

"No. 3. Two lines in diameter."

Let us now see how Perrève advised the instrument to be used:—

"After having selected a dilator of a size proportioned to the diameter of the narrowing, the surgeon places the patient upright, the back bearing against a verticle plane, the wall for example; then, after having placed himself before him, one knee flexed on the ground, he seizes the penis between the thumb and index finger of one hand, with the other holding the dilator, as we hold an ordinary sound, and without employing more force than we employ for holding a writing pen, he carries the instrument into the urethra.

"The horizontal position of the patient interferes with the liberty of movement of the surgeon; and, rendering thus his attitude constrained, it also assuredly interferes with the accuracy of the perceptions of touch while sounding. Moreover, the pressure which the buttocks in this position exercise on the canal, ought to diminish its diameter, and change, perhaps a little, its natural direction. Nevertheless, we may sound in the bed, as long as we experience no arrest; but as soon as a serious stoppage presents itself, we must place the patient upright."

"EXPANDING OF THE DILATOR."

"When the dilator is in the urethra, and when nothing more is to be done than to proceed with its expansion, we place the forcer on the conductor; then, keeping the instrument fixed with one hand, with the other we push the tube between the blades, until we feel it arrested. This step executed, we fix the index and middle finger of each hand against the first or the second clamp of the instrument, while we place the thumbs behind the handle of the forcer, as we see (Fig. 3); then, without disturbing the hands from their position,

and by approximating the thumbs to the clamp by the simple flexion of the palms of the hands we push the forcer between the blades, either *at once*, or by several repetitions—at once, if during the progress of the forcer, the patient does not complain of suffering; at several repetitions, if the sensibility of the patient requires momentary suspensions; for here is the point which should guide the operator when he is expanding the dilator, and he should stop during some minutes, every time the patient complains of the occurrence, or of the approach of a real pain.

"When the forcer is pushed home, we leave it *in situ* during some minutes; then we withdraw it, and next proceed with the extraction of the dilator."

But if the shafts or blades are delicate, and if there is any remarkable resistance to the extraction of the forcer, he recommends the dilator to be removed without previous removal of the forcer.

Perrève did not perform the maximum dilatation at the first *séance*. He usually allowed an interval of three or four days between each forcing. Indeed, he states, that an interval of eight or ten days may be allowed to elapse between one *séance* and another without the least inconvenience.

"SIMPLICITY OF THE INSTRUMENT."

"In respect of simplicity our instrument fully satisfies the greatest exigencies of surgery. In effect, what more simple than my dilator? *Two metallic blades* gradually separated by a conical mandrel, which is nothing else than a wedge—that is to say, the machine the most elementary of machines."

"SOLIDITY."

"My instrument presents a solidity much superior to that which a urethral dilator can require, since the smallest, No. 1, raises, without undergoing the *least deformity*, a weight of *thirty-six pounds*, when it has been placed under similar conditions to those in which it is situated when we are operating upon a stricture.

"By means of my dilators the dilatation is infallible, rapid, mathematically appreciable.

"*Dilatation infallible*.—Once the blades are in the canal, who can doubt the dilatation by the wedge, when we know that this can triumph over a resistance of thirty-six pounds at least.

"Is it necessary to point out the *security* with which we may force the wedge home? Well, who, on proceeding with the expansion of the dilator, need for a single moment dread a deviation of the forcer, when this last is *constantly maintained by a conductor and clamps, which conduct it always according to the axis of the canal?*

"Need I remark that my proceeding realises the great surgical maxim—*tuto, cito, et jucunde?*

"So few relapses are possible, provided that sounds are subsequently passed, that if there is a good deal in curing an actually existing malady, *tuto, cito, et jucunde*, it is much greater still to cure it, *tuto, cito, jucunde, et aeterno.*"

When we compare the dilator used by Mr. Holt, with Perrève's original and ingenious instrument, how pardonable was the expression of the latter, that he had "carried dilators to the utmost limits of perfection?"

"It evidently follows," he observes, "that to accomplish results in the best manner possible, in employing my dilator,

* B. Straight dilator with forcer *in situ* on conductor. A little under half real length. Traced and engraved from Perrève's original plate, by William Oldham.

Fig. 3.*

* Traced and engraved from Ferrè's original plate, by William Oldham.

Fig. 5.*

Fig. 4.*

* 1. Large end of M. Perrève's dilator, drawn to scale from Perrève's original plate, and engraved by W. Oldham.
D.E., Blades; F.F., Fores; d.d., Conductor; c.c., Clamps.
" 2. Vesical end of M. Perrève's dilator, drawn to scale from Perrève's original plate, and engraved by W. Oldham.
D.E., Blades; F., Forcer; d., Conductor.

* The instrument for what Mr. Holt enunciates as the new method of treating stricture of the urethra, and which instrument Mr. Philip C. Smyly asserts, "the profession owes entirely to Mr. Holt!"

we employ not only an excellent instrument, but an instrument for which no other can be preferred.

"If one can arrive at the last term of the conclusion, a little forced perhaps, I should say: what could you wish more?"

"My dilator restores the canal to its natural calibre;

"It restores it as quickly as possible;

"It restores it without change of organisation;

"It restores it without causing the patient to run any dangers;

"It restores it for ever, if the patient, after the treatment, uses the precautions recommended."

"RESUME OF THE PRINCIPAL ADVANTAGES OF THE NEW PROCEEDING."

"The preceding observations (cases) having justified all we have said in detail of the qualities of the new procedure, let us reproduce these last under the form of *résumé* :—

"1. The instrument unites all the conditions of simplicity and desirable solidity.

"2. By it, dilatation is infallible, as rapid as we can desire it, it is mathematically appreciable.

"3. Our dilators being of metal, they are in the conditions of anatomical catheterism, so that in operating with these instruments, we can tell exactly everything we are doing during the manœuvre.

"4. By them the course of the urine is immediately re-established.

"5. By them dilatation can always be carried to its utmost limits.

"6. One hundred and fifty to two hundred applications of our instruments have demonstrated that their dilatation is innocent.

"7. It is sufficient to see them to be convinced that they may render relapses for ever impossible.

"8. And when, through the negligence of the patient, a

relapse occurs after the application of our instruments, the treatment of this relapse is always simpler, easier.

"9. The new procedure realizes the great surgical maxim—*tuto, cito, et jucunde*; it even goes farther, since it is capable of preventing relapses.

"10. Everything which we have just said applies not only to organic strictures, but likewise to all strictures of the urethra whatsoever" (the splitting of traumatic strictures is by some thought to be a new proceeding), "so that the treatment of urethral narrowings is actually reduced to unity."—*Traité des Rétrécissements organiques de L'Urètre. Emploi Methodiques des Dilatateurs Mécaniques dans le Traitement de ces Maladies.* Par Victor Perrève. A Paris. 1847.

Fig. 4 represents both the handle and the vesical, ends of Perrève's dilator, with portion of the wedge or forcer between the blades. And if those gentlemen who feel interested in the matter will compare these delineations with representations, in the last edition of *Druitt's Surgeon's Vade-Mecum*, for instance, of similar parts of the instrument Mr. Holt uses, they will at once see there can be no essential difference between the dilator Perrève described and illustrated in 1847, and the "new (?) Stricture Dilator" of Mr. Holt, represented in the two editions of his memoir, which appeared in 1861 and 1863 respectively.

This is rendered very evident also by Fig. 5, which is a reduced representation of Mr. Holt's "new Stricture Dilator," (?) with forcer on conductor between the blades, and a separate forcer, for comparison with Fig. 1.

Having now given my proofs that I was strictly correct in calling by the name of Perrève the instrument used by Mr. Holt as a "new Stricture Dilator," I leave it to the candid and generous-minded reader if the so-called Holt's dilator, is not in every essential particular a counterpart of Perrève's.

It appears to me, then, that there was no justification whatever, for your correspondent's conclusion, that we are indebted for the instrument known as Holt's "entirely" to the latter gentleman, while he at the same time concedes that Mr. Holt acknowledges his having borrowed "the idea" of the dilator from that of M. Perrève. And here I demand that your correspondent will have the goodness to point out in what portion of Mr. Holt's memoir, which has now run through two editions (1861 and 1863), such an acknowledgment or mention of Perrève's name is to be found?

Should an acknowledgment of the kind have been published in any of the periodicals, and have been omitted in both editions of his memoir, I must confess, to use the mildest expression, justice has not been accorded to the inventive genius of Perrève.

In conclusion, let me recommend Mr. Philip C. Smyly, the next time he arrogates to himself the unenviable office of publicly accusing a professional brother of "mis-statement," to take care that he is better acquainted with his subject than he has proved himself to be with, the history, component parts, and mode of action, of Victor Perrève's "practical, useful, and invaluable instrument."—I have the honour to remain, sir, your very obedient servant,

B. WILLS RICHARDSON.

EPISTAXIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Upon reading in your issue of the 28th November, 1866, a paper on "Epistaxis, with its Treatment," by Dr. Thomas Ballard, Vice-President of the Harveian Society of London, read before the meeting of that Society on the 1st of November, I was struck with that gentleman's plan of removing the plug from the posterior nares when the mouth-string intended for that purpose was obliged to be cut off on account of the uneasiness it caused the patient, and thereby causing a difficulty in its removal. Dr. Ballard's plan for removal of the plug, under such circumstances, was—"A string was passed through the nostril with the aid of a piece of catheter, as at first, and then the anterior extremity of this was tied to the string hanging from the nostril; it was only necessary then to pull upon the posterior end, and the direction of the original string was reversed, and the plug immediately withdrawn." From the simplicity of this plan he considers that the mouth-string or posterior-string "may, in all cases, unhesitatingly be cut away," in which I fully concur, as I believe it to be useless. I have several times had to plug the posterior nares for epistaxis, and lately have

never used the mouth-string on account of its inconvenience to the patient; but the method of removing the plug that I have used, which suggested itself to me some time ago, is somewhat different, perhaps more simple, and decidedly most satisfactory and immediate; it is this—the anterior or nostril-string should be put through the hole or eye at the end of the spring of Bellocq's sound, the instrument I prefer (as a needle should be threaded), and the sound then passed along the nostril-string to the plug, that string being held sufficiently tense; then the sound pressed as firmly as necessary to dislodge the plug, which appears in the mouth on the end of the spring; when that part of the instrument is pushed well into its canula, the plug may then readily be seized by the fingers of the operator and withdrawn. For those who use Bellocq's sound this is, I conceive, the most simple operation.

In either case the mouth-string may, I consider, be done away with as an unnecessary inconvenience. Should there be two anterior or nostril-strings attached to each plug (which is a decided advantage in afterwards plugging the anterior nares), it will be sufficient to pass one of them through the eye of the spring.—I am, sir, your obedient servant,
JOHN H. CHAPMAN.

CASE OF ASIATIC CHOLERA

TREATED BY LARGE DOSES OF CALOMEL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As the cholera is still prevalent here, I beg to enclose a severe case treated principally with large doses of calomel, and which occurred in Table Bay, Capetown, South Africa, in 1862, which you will oblige me by inserting at your earliest convenience.—I am, sir, your obedient servant,

CHARLES H. ROBINSON.

On the 20th December, W. D., an engineer, aged 33, a remarkably healthy man, applied to me about eight o'clock, A.M., suffering from Asiatic cholera. He had been sick the greater part of the night, vomiting and passing stools of the looest kind. When I saw him his pulse was frequent and very feeble, surface of the body was colder than natural, and the voice low and faint; there was a *shrinking* of the body, and the countenance was pale, anxious, and *contracted*. On examining the vomited matter, I found those peculiar white little bodies like *rice*, which belong so essentially to this disease.

He was at once put to bed and a dose of an astringent mixture (principally composed of acetate of lead and acetate of morphia) was given at once, to be repeated after each liquid evacuation; and ten minutes after the first dose he took half a drachm (thirty grains) of calomel in a powder, turpentine stupe applied to abdomen, and hot bottles to feet.

21st December, nine o'clock, A.M. Bowels still loose, and vomits occasionally, but nothing like what it was before. Continue astringent mixture. Feels somewhat better; pulse slightly improved. Another half drachm of calomel was given at nine A.M. and at four P.M. the same quantity was taken, when it was discontinued, the purging and vomiting having ceased since nine A.M., and also because his mouth begins to feel somewhat sore. Next day the salivation was very severe, and for a day or two after this he bled a good deal from the gums and palate, but by giving internally five grains of chlorate of potash, four times daily, and using a wash composed of two drachms of chlorate of potash to eight ounces of water, besides occasionally painting the ulcerated parts with borax and glycerine lotion, the salivation was completely stopped on the 26th inst., and on the 1st January he was perfectly recovered, and the following day was able to attend to his duty.

On the 24th inst., as his bowels had not been moved for some time (three days), I gave a moderate dose of castor-oil, and a natural motion was the result.

The whole time he was under my care he took for the first plenty of strong beef-tea, broth and soups; syrup of lemon was allowed *ad libitum* as a cooling drink, his thirst being great and the weather extremely warm, and for the first three days half a bottle daily of brandy was given to him.

P.S.—He took altogether one and a half drachms (or ninety grains) of calomel in three doses, in the space of about thirty hours, which may appear extremely large doses, but the state of collapse he was in when I saw him, I considered warranted the treatment pursued.

NOTES OF LONDON PRACTICE.

We had an opportunity of seeing Mr. Paget, one of the earlier days of the month, perform the operation of amputation of the tongue, or rather removal of so much of this organ as could be reached with the loop of the ecraseur. The operation, as explained to us, was one of no small difficulty, from the trouble of applying the ecraseur far back enough, as the disease was very extensive—one of those irregular, rugged, unyielding hard lumps or knobs, the mucous surface puckered and rigid—true cancer, only to be treated by removal. Mr. Paget had the man placed under chloroform; for, as he explained to his class, he is now not afraid of the gurgling in the throat or bleeding from an amputated tongue. The knife alone may lead to hæmorrhage; though of this, the experience of Sir W. Fergusson, as well as Mr. Paget and other London surgeons, seems to be that the old ideas of bleeding from the tongue were exaggerated, copied from one book into another, without inquiry. The small amount of bleeding, in the present case, was at once arrested by a touch or two of the actual cautery. The man bore the chloroform very well, and though, to a casual looker-on, he might have appeared once or twice on the point of suffocation, his throat, so to speak, full of blood and mucus, yet he was not in the least danger, while the irritability of the larynx was not diminished or the chloroform not pushed too far.

Medical News.

APOTHECARIES' HALL OF LONDON.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Nov. 29th:—

Palmer, William Grimes, Loughborough.
Rainbow, Frederick, Lower Norwood.
Richards, William Joseph, Redruth, Cornwall.
Waller, Arthur, Milner-square, Islington.

The following gentlemen also on the same day passed their first examination:—

Bedford, Charles Frederick, St. Thomas's Hospital.
Causton, William Henry, London Hospital.
Jones, George Frederick, London Hospital.
Newth, Alfred Henry, St. Thomas's Hospital.
Rendle, Richard, Guy's Hospital.
Saunders, Thomas Dudley, Bath United Hospital.

CHOLERA having ceased, clean bills of health are granted to vessels sailing from Constantinople.

DR. BREWER, of Westminster, is a candidate in the Liberal interest for Colchester, Mr. Serjeant Ballantine having retired.

At a recent meeting Mr. Simon, F.R.S., was nominated by the Council of the Pathological Society for the next presidency. The election will take place early in the year.

At the Obstetrical Society the council has nominated Dr. Hall Davis president, subject to confirmation by the society in its election meeting in January.

The quarterly court of the governors of the Hospital for Consumption, Brompton, was held lately, and from the report read it appears that, since the opening of the building in 1846, 13,298 in-patients and 90,688 out-patients had been under treatment.

On the 5th inst. Dr. Belcher was elected an Honorary Member of the Cork Cuvierian and Archaeological Society; and on the 6th inst. the same gentleman was elected an Honorary Member of the Cork Literary and Scientific Society, having previously been elected an Honorary Member of the Medical Society of Cork, in which city he was one of the physicians to the Fever Hospital, previous to his removal to Dublin some years ago.

THE PARIS ACADEMY OF MEDICINE.—The Section of Accouchements presented to the Academy a list of three accoucheurs—MM. Tarnier, Joulin, and Mattei—whence to select one to fill up the vacancy. That learned body, however, probably thinking that the mere accoucheurs, six in number, are numerous enough in the Academy, added the names of MM. Barthez and Bernutz, the one well known in relation to diseases of children, and the other in relation to diseases of women. M. Barthez, the co-editor with the late Riilliet of the best work in the French language on the diseases of children, was elected by the votes of fifty-six of the seventy-five members present.

Notices to Correspondents.

Dr. MacMahon.—Your letter gave no decided opinion, nor any better reason for your views than intemperate vituperation. It was, therefore, not inserted.

Communications, &c., received from Dr. Oppert, Mr. Dallas, Dr. Lory Marsh, Messrs. Street, Brothers, Messrs. Burgess and Son, Dr. George Gibbs, Mr. Hayward, Mr. Mitchell, Mr. Baxter Langley, R. S., Liverpool; Dr. Hearne, Dr. Kiad, &c., &c.

ERRATUM.—In Mr. Richardson's reply to Mr. P. C. Smyly, Woodcut Fig. No. 4 has been, in the hurry of going to "press," unfortunately reversed.

Appointments.

ANDERSON, A. M., M.D., has been appointed Resident Medical Superintendent to the Dundee Royal Infirmary.

CLAPTON, E., M.D., has been appointed Physician to the Magdalen Hospital, Blackfriars-road.

DAVIDSON, A., M.B., has been appointed one of the Honorary Surgeons to the Liverpool Dispensaries.

FRY, F., F.R.C.S.E., late Senior Surgeon, has been appointed Consulting Surgeon to the West Kent General Hospital, Maidstone.

STUART, W., M.D., has been appointed Visiting Surgeon for Woolwich and the London Lock Hospital.

WILKS, S., M.D., has been appointed Physician to Guy's Hospital, and Lecturer on Clinical Medicine.

ADDENBROOKE, Mr. E. H., has been appointed House-Surgeon to the Birmingham and Midland Free Hospital for Sick Children, vice Dr. Owens, resigned.

AITKEN, L., M.B., C.M.Edin., has been appointed Resident Clinical Assistant to the Hospital for Consumption and Diseases of the Chest, Brompton.

ANNANDALE, T., L.R.C.S.Ed., has been appointed a Consulting Surgeon to the Infirmary, Newcastle-upon-Tyne, on resigning as Surgeon.

ARNISON, C., L.R.C.P.Ed., has been appointed Medical Officer for the Stanhope District and the Workhouse of the Weardale Union, Durham, vice G. Arnison, L.R.C.P.Ed., deceased.

LAND, Mr. W. J., has been appointed Resident Medical Officer to St. Mary's Hospital, Paddington.

LONGSTAFF, C., M.D., has been appointed Assistant-Surgeon to the Royal South Hants Infirmary, Southampton.

RAMSKIL, J. S., M.D., Assistant-Physician to the London Hospital, has been appointed Physician, vice P. Fraser, M.D., resigned.

SCOTT, G., M.D., has been appointed Assistant-Physician to the Royal South Hants Infirmary, Southampton.

THORP, D., L.R.C.P., late Resident Surgeon-Accoucheur to the Birmingham General Dispensary, has been appointed House Surgeon to the London Hospital.

WHITTAKER, Dr., has been elected Medical Officer for the Broadway Dispensary District of the Wexford Union, vice A. Hobson, M.D., resigned.

Vacancies.

Dover Hospital and Dispensary—Resident Medical Officer.

JAMES DUDGEON AND SON, AGENTS,
113, GRAFTON-STREET, DUBLIN.

SAINT PANCRAS, MIDDLESEX.

ELECTION OF RESIDENT SURGEON TO THE WORKHOUSE AND INFIRMARY.

CCANDIDATES, to be eligible, to be between 25 and 40 years of age, Single Men, or Married Men without children dependent upon them, and must possess the Legal Registered Medical and Surgical Qualifications. Salary £160 per annum, with an increase of £10 every two years to a maximum of £180 per annum, Vaccination Fees, and Board and Residence in the Workhouse. There are also other fees incidental to the Office. Appointment determinable by one month's notice in writing, or salary in lieu of Notice, from any time by either party, without any allowance for Board and Residence. Should a married man be elected, his wife is to reside with him in the Workhouse, and he is to pay £20 per annum for her Board. The person appointed will be required to commence duty immediately after election. Applications in Writing, and Testimonials of recent date (not exceeding six), and Certificates of qualifications, to be left here before two P.M. on Saturday the 15th inst. Candidates to attend at a Meeting of Vestry, to be held here on Monday the 17th of December inst., at three o'clock in the afternoon. No travelling or other expenses will be allowed for any attendance.

By Order, FRANCIS PLAW, Vestry Clerk.
Vestry Offices, Pancras Road,
December, 1866.

DARTFORD UNION.

MEDICAL OFFICER.

THE GUARDIANS of this Union will, on the 15th day of December instant, receive applications from, and if necessary then proceed to the Election of a person duly qualified, according to the General Order of the Poor-Law Board, to become the Medical Officer of District No. 1a, comprising the Dartford Union Workhouse.

The salary will be £65 per annum, with such sums in addition as are specified in and allowed by the Orders of the Poor-Law Board as extra Medical Fees. The Medical Officer will be required to reside within the town of Dartford. The engagement to be subject to the approval of the Poor-Law Board, and to any variation which may hereafter be made with reference to the duties of a Medical Officer.

Applications, with testimonials, to be forwarded to the Clerk's Office in Dartford, on or before Friday the 14th day of December, inst. Personal attendance of the Candidates at their own expense at the Board-Room of the Workhouse, on Saturday the 15th day of December, inst., at Twelve o'clock at noon is required.

Dartford, Kent, 1st December, 1866. JOHN HAYWARD, Clerk.

ABBEYLEIX UNION.

BALLINAKILL DISPENSARY DISTRICT.

THE COMMITTEE OF MANAGEMENT of the above Dispensary District will, at their Meeting on MONDAY, the 17th DECEMBER next, appoint a properly qualified MEDICAL OFFICER, in room of the late lamented Dr. James Nelson Walsh, at a salary of £100 per annum, exclusive of Registration and Vaccination Fees.

Testimonials to be lodged with me on or before Nine o'clock on the day of election.

MATTHEW P. COMERFORD,
Honorary Secretary.

Woodville, Abbeyleix, 28th Nov., 1866.

BALLINROBE UNION.

IN consequence of the resignation of Dr. ROUGHAN, who has been appointed Medical Poor-Law Inspector, the Committee of Management of the Cang Dispensary District will, at their Meeting, to be held at the Dispensary, Cross, on Friday, the 21st day of December, 1866, proceed to the appointment of a Medical Officer for the District, at a Salary of £100 per annum, exclusive of Registration and Vaccination Fees.

Candidates for the office must possess the professional qualifications prescribed by the Poor-Law Commissioners.

Applications from Candidates (who are required to be in attendance) accompanied by testimonials and qualifications, will be received by me up to One o'clock in the afternoon of the above-mentioned day.

The person appointed will have to reside within the District.

By order of the Committee,
G. R. STAREY, Hon. Secretary.

Castletown, Cang, December 4, 1866.

ARMY MEDICAL DEPARTMENT, December, 1866.

ACOMPETITIVE EXAMINATION of CANDIDATES for COMMISSIONS in the MEDICAL DEPARTMENT of Her MAJESTY'S ARMY, will COMMENCE at Chelsea Hospital, on Monday 11th February, 1867, at 10 o'clock A.M.

SUBJECTS OF EXAMINATION :

OBLIGATORY.

Anatomy and Physiology, Surgery.
Medicine, including therapeutics, the diseases of women and children, chymistry and pharmacy, and a practical knowledge of drugs.

OPTIONAL.

Comparative Anatomy, Zoology, and Botany, with especial reference to Materia Medica.

Candidates having the necessary qualifications to practise Medicine and Surgery under the Medical Act, and who are unmarried, and not under 21 nor above 25 years of age, are eligible to attend.

Applications for the printed form (which must be filled up by intending competitors before their names can be placed on the list of candidates) should be made in writing to the Director-General of the Army Medical Department, War-office, London.

J. B. GIBSON, Director-General.

Society for the Relief of Widows and Orphans of MEDICAL MEN.—Founded 1788.—Incorporated by Royal Charter 1864.—The Members are reminded that a QUARTERLY COURT OF DIRECTORS will be held on the 9th January next, at which Candidates for admission into the Society can be proposed. It is desirable that the Forms of Proposal be filled up and forwarded to the Secretary at least a week before the meeting. The form of Proposal may be obtained of the Secretary. The benefits of the Society are restricted to the families of deceased Members of not less than two years' standing. The Secretary attends at the office every Wednesday and Friday from 4 to 5 o'clock.

S. W. J. MERRIMAN, M.D., Secretary.

53, Berners-street, W., 30th November, 1866.

SURGICAL SOCIETY OF IRELAND.

THE Meetings of the Society for the Session 1866-67 will take place at the Royal College of Surgeons, on the undermentioned Evenings, at Half-past Eight o'clock precisely:—

- 1867—Friday, 4th January.
- " Friday, 18th January.
- " Friday, 1st February.
- " Friday, 15th February.
- " Friday, 1st March.
- " Friday, 15th March.
- " Friday, 29th March.
- " Friday, 26th April.

Members who intend to read Papers before the Society are requested to inform the Secretaries, in writing, of their intention a few days previously.

Discussion on any Paper is not permitted unless the writer calls for it or desires it.

When the Contributor of a Paper wishes that the Secretaries should read it to the Society, he will please forward it to them some days before the Meeting.

Except under special circumstances, no Member can be permitted to occupy the Meeting in reading a Paper for a longer period than half an hour; and the Society will not be held responsible for any opinions advocated in the communications read. Neither can a Member be allowed to speak for more than ten minutes, during a debate relative to a communication.

After a Paper has been read it becomes the property of the Society, for publication in its proceedings.

The exhibition of recent morbid specimens is allowed precedence of all other communications; but a specimen cannot be considered a report unless it has been removed from the body within the fortnight immediately antecedent to the Meeting.

Each Member of the Society, being a Subscriber of 5s. to the Refreshment Fund, is entitled to as many Tickets for Visitors as he may require, at 6d. each.

Naval and Military Surgeons are admitted as Honorary Members of the Society on sending their names to the Secretaries.

None but Physicians or Surgeons are admitted to the Meetings of the Society.

CHARLES BENSON, M.D., } Honorary
B. WILLS RICHARDSON, F.R.C.S.I., } Secretaries.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

AN ADDRESS,
DELIVERED BEFORE THE
MEDICAL SOCIETY OF THE KING AND QUEEN'S
COLLEGE OF PHYSICIANS IN IRELAND,
At the opening of the Session 1866-67.

By WILLIAM STOKES, M.D., D.C.L., F.R.S.,
PRESIDENT OF THE COLLEGE, &c.

GENTLEMEN,—It is just half a century since our parent Society, The Association of the King and Queen's College of Physicians, was formed. When I joined it our place of meeting was a very small room, over the shop of Hodges and M'Arthur, which served for the purposes of a Reading-room every day, while the monthly meetings held at night were crowded,—not, so much, by reason of the number of Members, as from the narrow space in which they had to assemble.

It was an interesting place, like the conversation-room of a club, and many of the senior members of the profession frequently resorted to it.—Brooke, John Beatty, Mills, Read, Brien, Harty, and the Venerable Teeling, with his quaint scholastic lore, his snuff-box, and gold-headed cane, did all the charm of manner belonging to the gentleman of the last century. He was the father of the Profession, and I remember his describing to me the lectures of the *ecq d'Azur* on Phlogiston, which he had himself attended. At the monthly meetings papers were read, and not less than five volumes of transactions were printed. They are on the table before you.

On referring to the minute-book of the Association, it will be seen that its first meeting was summoned by Dr. Brooke, and held at his house, on the 3rd of July, 1816. It was attended by twenty-eight physicians, among whom were Cheyne, Stoker, Clarke, Allman, Todderick, Hopkins, John Crampton, Jackson, Edward Percival, Egan, Teeling, Boyton, and Grattan, still in the enjoyment of health and vigour. On the third meeting the Association determined to occupy the small supper room at the end of the building. On the 18th of September, 1817, a small room at the back of the shop of Hodges and M'Arthur, bookbinders, in College-green, was engaged, and there the Association met for some years.

It continued to flourish for many years, when it declined, and at last virtually ceased to exist. In 1850, it was renewed and re-organised, still keeping its old name, until two years ago, when, with other changes, its name was altered to that of the Medical Society of the King and Queen's College of Physicians. This was in 1864, so that we have now entered on the Third Session of the remodeled Society. We have now four Medical Societies in Dublin: The Pathological Society, founded for the purposes only of observation, demonstration, and record. At meetings debate is not permitted. We have the Surgical and Obstetrical Societies, and lastly, the Medical Society of this College. At the meetings of the first three of these bodies students are admitted, under certain limitations, a most important element in their constitution; and in the Obstetrical Society, I believe that senior students are even permitted to be members. I am not here to advocate any changes in the laws of our Society, yet it seems to me that a certain class of students might have the privilege of attending lectures, such as the holders of medical scholarships and exhibitions, and the resident pupils of hospitals, and those who have obtained the gold medals of the Pathological Society. I have said that the original Association brought out five volumes of transactions. The establishment of the Dublin Journal of Medical Science was followed by the

cessation, not only of this work, but of the more important one, The Dublin Hospital Reports, founded by Cheyne, in 1817—a work which gave to Irish Medical literature a weight and tone which has been long preserved, and which should never be departed from.

There is now no want of means of publication for medical papers in Dublin, and for that class of memoirs which may be too extended or weighty to be fitted for a weekly periodical, we are provided in the *Quarterly Journal*. It seems to me that the efforts of this body should be devoted to the support of our established periodicals, rather than to the foundation of a separate journal; yet this I may say, that should the Society ever attain such a position as to warrant a separate publication of their transactions, it would be well to follow the plan of not being tied by time as to the appearance of the volume, but of only producing it when there was a sufficient amount of papers of a certain class to fill it. In this era of competition men wish to let their productions see the light with little delay. Immediate notoriety is sought for, and so it happens that the interests of science, and the subsequent fame of the author, are liable to suffer. Do not suppose that I underrate the advantages of medical periodicals, I only wish to shew the utility of both systems to medical literature. By a recent arrangement all subscribers to the reading-room are members of the Society; and it is greatly to be desired that every fellow and licentiate resident in or near Dublin should be enrolled on its lists.

Our last two Sessions have been very fruitful, and many memoirs of the greatest practical value have come before us. Of these, one of the most remarkable was that by Dr. Brown-Sequard, on the advantages to practical medicine and surgery of physiological study. It was illustrated by a number of examples principally of traumatic injuries of the spinal cord, and again of asphyxia and of syncope, and contained many new and striking views of diagnosis.

In the careful study of human and comparative physiology, practical medicine must advance, first, in the line of diagnosis, and next in that of treatment. And it would be rash indeed to predicate the limits of these improvements.

While the minds of many investigators are directed to these subjects, another line of inquiry is daily becoming prominent. It is that of experimental pathology, in which, by the study of the influence of organic compounds on the economy it is sought to discover, *the laws which govern the production of disease*. The researches of Richardson and of Weber promise important results. Septic poisons and other re-agents are introduced into the veins of animals, and the symptoms and pathological changes carefully noted, and in this way disease, artificially produced by known causes, is compared with the zymotic affections of man. I may instance the action of sulphuretted hydrogen in producing many, if not all, the symptoms of cholera. I give this as a solitary instance. So also in pyæmia, the experiments of Weber and Urfe shew that the blood of an animal, in which pyæmia was artificially induced, was capable, when injected into the veins of another, of inducing a similar pyæmic condition.

As, in one respect, belonging to this subject, the labours of Professor Haughton, on renal pathology, require especial notice, as well as those on the expenditure and renewal of muscular force. In this Society the last of his communications was as to a method of determining the amount of urea and of inorganic matter in a given quantity of urine. His formulæ are simple, but have been derived from a large series of observations and an extensive tabulation. His method, by which, from the specific gravity, the amount of either product is determined, will prove of great advantage, not alone in investigations as to the origin of disease, but to the daily practice of medicine.

One of the most interesting papers is that by Dr. Foot, on chromidrosis, or coloured exudations of the skin. After shewing that in no case can these appearances be traced to the passages of the blood globules through the capillary wall, that is, to the altered colouring matter of the blood that these appearances are to be traced.

In the case of yellow sweating, which may precede any jaundiced state of the skin, it seems probable, from the experiments of Wirchow and Funché, that it arises from a change of hæmatin into cholepyrrhin; and this throws light on the hue in pyæmia, in cases of chloroform poisoning, and that observed after the bites of venomous serpents. I would suggest to Dr. Foot whether a similar view might not apply to cases of typhus icterodes, and to yellow fever, in both of which anatomy fails to detect the causes of the jaundice. Certain it is that in the yellow fever, described by Dr. Graves and myself, in the epidemic of 1828 and '30, there was no hepatitis, the duodenum was not more congested than other parts of the alimentary canal, and there was no obstruction to the flow of bile. It is known that in cases of intense jaundice, none of the elements of bile, except the colouring matter, can be detected in the general system, and so it becomes probable that the chromogen of Frerichs, produced by the action of acids on the colouring acids of the bile, is the agent in changing the colouring matter of the blood. Time will not permit me to follow Dr. Foot through the rest of his valuable and suggestive paper, in which he deals with the history of the blue or black pigments, and shows the derivation of indigo secretions from the hæmatin.

In connection with Dr. Foot's paper, the case of Morbus Addisonii must be noticed as confirming the views of Dr. Addison and Dr. Wilkes; the case is one of great interest, yet it must be confessed, that the true nature of this singular disease is yet to be worked out. Looking at all the facts, the opinion that it is merely symptomatic of disease of the supra-renal capsules may be questioned, although *when formed it may be held to be diagnostic of that disease*. It may be that in its essence it is a chemical disease resulting from reactions, as yet but partially understood of different agents of the hæmating, and that the organic change is consequence rather than cause; indeed Dr. Hayden, in his admirable paper on Supra-renal Malasma, after shewing that tuberculosis in some form was the complicating affection in the proportion of sixty-two and a-half per cent., observes, that independently of the preponderance of strumous deposits in the capsules themselves, it would seem difficult to resist the conclusion, that in supra-renal malasma the diathesis is eminently strumous.

In papers on Practical Medicine the two past sessions have been very rich. Dr. Law has handled the subject of the strange tendency to symptoms of Cerebro Spinal disease which for two years and more has been seen. This is one of these phenomena still requiring much investigation. The epidemic tendency to focal disease. We have had some examples of this disease in the Meath Hospital. Some as a sequence in cases of sun-stroke, others occurring in progress of fever. In one is a case of that form of fever called by Dr. Lyons, the Black Death, the Medulla Oblongata was softened. The occurrence, as I said of this lesion, in so unusual a manner reminds us of the epidemic tendency to abscess of the liver which was so remarkable in Dublin in 1800.

Dr. Henry Kennedy has contributed a paper of great importance on the mixed types of fever. Here is a class of cases, which though not yet sufficiently dealt with by writers, is familiar to the experienced physician, and Irish Medicine is deeply indebted to Dr. Kennedy for this, as well as many other, additions to our knowledge of the healing art.

Dr. Kennedy holds to the view that there is no essential difference between Typhus and Typhoid, or Enteric fever, and that both may proceed from the same source. Without denying that a well marked case of Typhus differs from one equally well marked example of Typhoid, I confess that I have long inclined to opinions similar to those of Dr. Kennedy, as opposed to the views of some of the London and American observers. The difference and conditions of receptivity may account for one man getting typhus and another typhoid from the same poison; and it is often seen in our hospitals that when a whole family are together in the wards, every variety of fever may be seen among

them, it is more than *probable that the one exciting cause affected all*. Dr. Kennedy has shewn what all must admit, that enteric symptoms may exist with a petechial rash, and though I am not here to advocate or condemn his views, it will be admitted that they deserve the most grave consideration.

The researches of Dr. Grimshaw on the influence atmospheric heat and moisture on the prevalence of fever are examples of that scientific accuracy of observation which is every day lessening the conjectural state of medicine. In practical medicine we have had several important communications, such as those of Dr. Moore and Dr. Hayden on diphtheria, cases of puerperal foetid abscesses of the lung, of recovery from traumatic tetanus; and a case of foetid expectoration by Dr. Byrne, Dr. M'Swiney, and Dr. Moore; and a case of Empyema, successfully treated by the drainage tube of Dr. Gordon.

On the difficult and important subject of mental disease we had two papers—one by Dr. Madden, on the criminal responsibility of the insane, and another, by Dr. Eustace, on cases of insanity of difficult diagnosis.

Two more papers remain to be noticed: one on scrofulous pulmonary affections, by Dr. Halahan, and the other on case of congenital deficiency of the lower extremity, by Dr. Skipworth.

The last paper claiming notice is the account of the Endoscope, by Dr. Cruise. Originally described by Desormeaux, it was reserved for Dr. Cruise to make the instrument practically applicable; and so much has he made the instrument his own that, while Paris can claim to be the birth place for the stethoscope, Vienna the laryngoscope, and Berlin the ophthalmoscope, Dublin is entitled to the honour if not of the discovery, at least of the application, of endoscopy.

It is not saying too much to declare that for the diagnosis of diseases of the whole tract of the urethra, the bladder, the vagina, the uterus, the rectum, the nasal cavity, and pharynx, the endoscope may be placed on a level with the laryngoscope and ophthalmoscope in their special applications to diagnosis.

Nothing can be more honourable to Dr. Cruise than the way he speaks of the researches of Desormeaux, claiming little more than an improvement in the illuminating power of the instrument. *But this is the great point*; and the light of Dr. Cruise's endoscope, as compared with that of Desormeaux, is as daylight to twilight. This improvement is obtained in various ways, but principally by modifications in the composition of the fuel of the lamp; the use of the edge of the flame from a flat wick as an illuminator by which a great increase of power is obtained, and by mechanical arrangements, which give steadiness to the light. By it all changes in colour, as well as structure of all parts accessible to a straight tube are rendered visible; and Dr. Cruise anticipates that the endoscopic difficulties produced by the pharyngeal angle of the œsophagus and that of the cardiac orifice of the stomach will be overcome by optical arrangement.

The endoscope is further applicable in the case of wound especially in determining the presence or absence of a foreign body. Had Garibaldi been fortunate enough to have had Dr. Cruise on his medical staff at Aspromonte he would have been saved great suffering, and the cause of surgery some discredit. The endoscope is further applicable for exploring serous cavities after operation, as well as the lining membrane of cysts and abscesses.

In his enlarged and developed paper, Dr. Cruise gives many examples of the advantages, in no other way attainable, of this beautiful instrument. And as an illustration of its powers, he relates that Dr. Robert MacDonnell prepared a subject by opening the bladder, and introducing into it three substances, of a nature the most unlikely to be thought of, and respecting which Dr. Cruise was in total ignorance. He was then challenged to tell, by means of the endoscope, what were the articles in the bladder. In a few minutes he was able to do so, and to demonstrate them

They were a brass screw with a milled head, a short minie bullet, and a mass of plaster of Paris.

Let us now consider the application of physical diagnosis to the diseases of the eye, the larynx, the pharynx, and upper portion of the œsophagus—to those of the lungs and heart by auscultation, to those of the peritoneum liver and spleen, to the chemical diagnosis of affections of the kidneys and bladder, to the microscopic diagnosis, based on the examination of secretions and the blood, and to the endoscopic diagnosis of all urethral and vesical and uterine affections, of all diseases of the rectum, it must be admitted that in the replacement of uncertainty by certainty, the advance of medicine in the 19th century has been most marvellous. To be a proficient in all these means of diagnosis would be difficult or impossible to any single teacher; and while the observation of disease rendered fruitful by study—and therapeutical research must foster, as they have ever done, the foundation of the medical art, its teachers must inculcate a liberal and enlightened spirit, in reference to all collateral means in the search after the discovery and the nature of disease.

The memoir of Dr. Stearne, the founder, and first President of the College of Physicians, in the reign of Charles the Second, was read before the Society, by Dr. Belcher, to whose labours we were subsequently indebted for an account of the life of Sir Patrick Dun, to whom the foundation of the King's Professorships in the school of physic is due. Until the establishment of *The Dublin Quarterly Journal of Medicine*, under the editorship of Sir William Wilde, the biography of Irish physicians and surgeons was wholly neglected, and there was no feature of greater interest in the Journal, while under his auspices, than the lives, from his pen, of the former worthies of Irish medicine, of Mosse, O'Halloran, Mac Bride, and of Dun, and in recent times, of the gifted and lamented Curran. History is ever valuable, not merely the record of dynasties, revolutions and wars, to which class of record, written without reference to the social and intellectual state of a people, their progress in legislation, in arts and all humanizing influences, the name of an "old almanack" has been justly given by a great thinker. And if the history of the inner life of a people be valuable, so also is that of individuals who have been leaders in some good work for their generation. The history of nations, in fact, resolves itself into the history of individuals; and all true records of men of mark subserves the great end of enabling us, by the study of the past, to predicate the future, and to prepare ourselves for it.

It must be a source of gratification to Dr. Beatty that, during the two years of his Presidency, so much good work has been done—so much zeal shown; and all who know that true physician and distinguished gentleman, will hold with me, that our success is in no small degree due to the interest he took in the proceedings of the Society, and to the dignity and courtesy with which he filled its chair. Gentlemen, I feel that I have occupied your time too long. I cannot conclude, however, without alluding to a subject of deep interest to us all—I mean the approaching visit of the British Medical Association to Dublin. The members of this great and influential body, comprising most of the profession in England, have long desired to meet their Irish brethren in scientific and social communion. I am in a position to say that they look forward with great pleasure and hopeful anticipation to the meeting in Dublin, that seat of medical science and teaching. And their visit, the first of the kind since the foundation of the Society, will, independently of its scientific results, be a means of promoting good-will and mutual respect between the members of the profession in the sister countries and those of Ireland.

For it is a great and wise object of the Association to foster the friendly feelings of our brethren towards one another, to remove jealousies and suspicions, and to make that profession, whose first characteristic is charity and love of our neighbour—shewn in works unknown, uncounted of silent good, exhibit in the friendly relations of its members through the length and breadth of the land, the same prized and exalted qualities.

Its advent too will tend to improve the relations between the countries—to remove national prejudices, and by rendering the union of Great Britain with Ireland every day more real, carry out the desires of all loyal men.

ON EMBOLIC PHTHISIS AND TUBERCLE,

BEING THE SUBSTANCE OF SOME CLINICAL OBSERVATIONS

MADE BY

ANDREW CLARK, M.D., F.R.C.P.,

PHYSICIAN TO THE LONDON HOSPITAL.

DR. CLARK began by saying that there are many eminent physicians who still discuss the subject of pulmonary phthisis as if it were due to one uniformly recurring series of anatomical conditions; and he referred to a body of experimental and pathological evidence on the question sufficient to prove beyond the possibility of doubt that this view is quite unsound, and that plans of treatment based upon it, whilst occasionally right by accident, must always be wrong in principle, and often mischievous in their results. There are, he said, many different pathological conditions giving rise to the phenomena grouped under the name of pulmonary phthisis; and though improved clinical observation will in time enable us to recognize these distinctions during life, their recognition will never perhaps be so complete as after death. For the textural elements of the pulmonary alveoli are not distinctly expressed; one is seldom affected without the other; and the symptoms caused by pathological changes in an organ like the lung are more immediately related to damaged function than to the nature and seat of the disease. These are and always will be the great difficulties lying in the way of an accurate differential diagnosis. But much, he said, might be done to lessen these difficulties by a more careful study of the histories of cases of phthisis; and, whilst they are under medical observation, by a more minute and accurate record of their phenomena. The lung in relation to phthisis, he added, is much like the kidney in relation to Bright's disease. Under this designation are included several diseases differing in their nature and taking their origin in different tissues. Some are inflammatory—some degenerative—some specific; and whilst one arises in the cellular, a second arises in the fibrous, and a third in the vascular constituents of the organ. Science, continued he, has given to these distinctions a precision which has already exercised a favourable influence upon the practice of our art, and if carried into the diseases of other organs must greatly widen its resources.

Dr. Clark then proceeded to enumerate and explain the chief pathological conditions of the lung giving rise to the collection of symptoms grouped under the name of pulmonary phthisis. These are, according to him, as follow:—1st, semi-transparent grey tubercle; 2nd, primitive yellow (scrofulous or cellular) tubercle; 3rd, secondary yellow tubercle (that is, the tuberculization of retained secretions, accumulated structural elements, unabsorbed inflammatory and other deposits); 4th, fibrous degenerations (including the drunkards', masons', miners', and grinders' lungs); 5th, embolisms (of the larger vessel as well as of the capillaries); 6th, hæmorrhagic extravasations; 7th, syphilitic nodules; 8th, amyloid degenerations.

Dr. Clark considers the "grey granulation" to be the essential anatomical element of a form of phthisis quite distinct from all others, and of such great gravity as to merit the appellation malignant. It is distinguished during life, chiefly by the fewness of the local signs of disease as compared with the extent and profoundness of the constitutional prostration manifested by a quick and feeble circulation, an elevated temperature, and extreme debility. It is further distinguished from all other forms of phthisis by the singular fact experimentally proved by Villemin and himself, that its anatomical elements—grey

tubercles—are capable of being produced in the lungs of healthy animals by inoculation in almost any part of their bodies. Dr. Clark further alleged that in chronic cases these tubercles never killed by themselves but by their secondary effects, which he described as *intercurrent pneumonia, fibrous degeneration, fatty usure, and emphysema*.

After having discussed and exhibited specimens of the other forms of lung disease already specified, Dr. Clark proceeded to give the histories of some cases of embolic tubercle and phthisis, the chief features of three of which we subjoin:—

Case 1.—John Towhig, æt. 32, an A.B. in her Majesty's navy, was admitted into Haslar Hospital in January, 1849, for œdema of left leg and slight cough. In 1847 patient had a blow in his left groin, which was followed by slight swelling and pain. Three months afterwards the left foot began to swell, and kept swelled more or less from that time. During the previous six months the swelling had extended to the thigh. Two months before admission he began to cough, and occasionally to expectorate a little blood.

On admission the digestive organs were in fair condition. The urine was acid and loaded with lithates. The cardiac dulness was increased and a creaking leather sound accompanied the contraction of the ventricles at their base, but there was no murmur. There was slight dulness under both clavicles, and there the inspiration was broken or interrupted and the expiration prolonged. At several spots below this there were on both sides dull spots where respiration was almost inaudible. In no place was there tubular breathing or increased vocal resonance. There was dulness over the bases of both lungs behind, with feeble respiration and an occasional subcrepitant crackle. Patient had a teasing cough, dyspœna, and scanty purulent expectoration, streaked with blood. He had no headache or pain in the chest, but he complained occasionally of uneasiness in the left iliac region, and of numbness and formication in the limbs. The latter he ascribed to rheumatism, from which he had suffered severely on various occasions. Patient was subject to local sweatings: his feet and hands were always wet. Lately he had been losing flesh, strength, and colour.

The patient was allowed a generous diet, blistered from time to time, and put on quinine, iron, and cod oil. He never improved, however. About the middle of February he took typhoid fever, and died on the 9th of March.

Post-mortem Examination.—Body emaciated. Left lower extremity highly œdematous. Head not examined. Heart weighed nine ounces, and was around its base in front loosely adherent to the pericardium; valves and orifices healthy; a fibrinous-looking concretion about the size of a pea hung from the tip of the right auricle, and appeared to take its origin from a roughened spot in its lining membrane.

The lungs collapsed slightly on opening the thorax, and were at parts adherent to the chest. Anterior surfaces emphysematous; posterior and lower dark red and dense. In the upper lobes of both lungs were several yellowish-coloured friable deposits about the size of hazel nuts. Around some of these the lung substance appeared unaltered; around others there were zones of greater or less thickness, of what appeared ordinary red hepatization. In the middle part of both lungs, in addition to a few deposits, there were several small, smooth, rounded cavities, about the size of walnuts, containing yellowish curdy pus. These cavities, like the deposits, lay nearer the surface than the centre of the lungs, and in no respect, save, perhaps, in their contents, did they resemble the cavities found in tubercular phthisis. *No true grey tubercle was anywhere to be found.* The posterior and inferior portions of both lungs were in a state of complete collapse, and all the minuter bronchi traversing the collapsed parts were filled with vitreous, tenacious mucus, streaked with blood. Firm decolorized clots were found in several of the smaller branches of the pulmonary artery, some of which led to the yellow deposits, and others to the emphysematous

portions of lung. In sections of the deposits examined microscopically minuter branches of the pulmonary artery were seen containing plugs (emboli) similar to those just described. (Specimens from Dr. Clark's collection were here exhibited). The bronchial and cervical glands were enlarged.

Abdomen.—Liver large and pale. Spleen large and pulpy. Kidneys healthy. Ilium studded with round and oval ulcerations. The latter occupied the situation of Peyer's patches, had thin flattened margins, and rose from the circumference to the centre. The central matter was of a dark-brown colour, broken into nodules by intersecting fissures, and had somewhat the appearance of sloughs.

The left iliac vein for about an inch and a half in length was distended to more than twice its ordinary size by a reddish-white matter visible through the attenuated coats of the vessel. On laying it open the contained matter was seen to resemble as closely as possible a crumbly mass of old cheese steeped in watery blood. The mass smooth and rounded at its distal was rugged and broken at its proximal extremity; and though friable in the centre and at its extremities it was firm on its circumference and inseparably united to the lining membrane of the vein. On the distal side of the concretion (thrombus) the vein contained a healthy clot; on the proximal side it was empty. The adjacent artery was quite healthy.

In commenting upon this interesting and instructive case, Dr. Clark set forth what he believed to be the true order of events, and declared his conviction that upon the assumption of any other order the case was inexplicable. He considered that a local phlebitis issuing in an obstructive clot had been set up by the blow received by the patient in 1847; that in process of time portions of this clot having become detached, got with the venous blood into the right side of the heart, and were arrested in the minuter branches of the pulmonary artery; that these secondary clots (emboli) set up in their neighbourhood diseased actions which issued in the formation of the yellow deposits; that these deposits, under unfavourable conditions, broke down into small abscesses; and that in this state the patient was attacked with typhoid fever, which led to ulceration of the bowels, and put an end to his life.

Dr. Clark considers that cases like the one just narrated are not uncommon. He admits that it is rare to have such demonstrative proof of their nature after death; and he accounts for this by the general curability of such cases, the infrequency of post-mortem examinations in phthisical cases, and the neglect of definite points of inquiry when they are made. He further said that in experimenting upon animals by the injections of foreign matters into their veins he had often succeeded in producing *embolic tubercles*, though he had hitherto failed in producing embolic cavities.

Case 2.—(Reported by Mr. R. C. Sanders.)—Eliza Taylor, æt. 24, married, was admitted into the London Hospital under the care of Dr. Andrew Clark, in August, 1866. Was confined three months before admission. Ten days afterwards suffered pain in the pelvis and was unable to extend her limbs. A fortnight later the legs began to swell, and the pain and difficulty of movement subsided. Three weeks before admission she began to be short-breathed, to have pain in the chest, to cough rather frequently, and to spit up a little mucus streaked with blood. Patient was a thin, pale, delicate-looking woman, with large pupils, a transparent skin, and prominent superficial veins. The tongue was eroded, there was some pain after food; flatulence and confined bowels. No uterine discharge; urine free from albumen, intensely acid, and loaded with lithates. Heart sounds normal; pulse 96, small; respiration 28 per minute. Chest rose unsymmetrically on inspiration. Over the right second rib, about two inches external to the sternum, there was marked dulness to the extent of a crown piece; a second and similar dull spot existed just outside the left breast; and a third near the inner edge of the spine of the right scapula. In

all these places the inspiration was loud, blowing, and divided; the expiration prolonged, loud, and accompanied towards its close by a dry crackling roushus. Vocal fremitus diminished; resonance increased. At a fourth spot under the right breast there was blowing respiration and inspiratory moist crackle without dulness or increase of vocal resonance. There was no pain in the chest, but a constant sense of tightness and oppression. Patient suffered also from persistent coronal headache, and occasional confusion of thought and giddiness. There were no night sweats. Both legs were swollen, tense, polished, of a peculiarly intense white colour, and pitted very slightly on pressure. Pressure was ill borne over the lower part of abdomen, but no tumour could be detected.

Dr. Clark considered the case to be one of ilio-femoral thrombosis with secondary embolic deposits in the lungs. The patient was put upon full diet, and ordered to drink freely of bland fluids. An effervescing ammonia mixture with nitrate of potash and iodide of potassium was directed to be taken four times daily, and she was instructed to keep her lower extremities in a warm soda bath for a couple of hours twice a day. The bowels were freely opened with castor-oil.

Within three days from the adoption of this treatment the patient had greatly improved. The swelling of the legs had almost entirely disappeared, and the urine threw down no sediment on standing. The chest symptoms were much the same. The soda baths were omitted; the mixture was continued; mustard plasters were ordered to the chest. Two days after the omission of the soda baths the swelling returned in the left leg. The baths were therefore resumed, and the leg was ordered to be kept bandaged in the intervals. In four days from this time the swelling again subsided and did not return. At the end of three weeks the pulmonary symptoms had almost entirely disappeared. The alkaline mixture was replaced by quinine and iron, and the patient was shortly afterwards discharged cured.

Dr. Clark pointed out the great benefit which, in this case, was derived from warm soda baths, and said that in all similar cases, following parturition or not, he knew no treatment so rapidly efficacious in reducing the swelling as the use of soda or potash baths, followed by bandaging of the affected limbs. These baths were made by adding bicarbonate of soda or potash to warm water in the proportion of half a pound to the gallon. The limbs should be immersed for at least a couple of hours at a time, and the solution should be kept warm.

(To be continued.)

SOME OBSERVATIONS ON
THE TREATMENT OF ACUTE ABSCESS
OF THE
PROSTATE GLAND, POINTING TO THE
RECTUM.

By JOHN HAMILTON,

SURGEON TO THE RICHMOND HOSPITAL, AND TO SWIFT'S HOSPITAL FOR
LUNATICS.

ACUTE inflammation of the prostate gland is not a very uncommon occurrence at a late period of gonorrhœa, and more rarely in stricture, the inflammation of the mucous membrane behind the stricture extending to the body of the gland. When it terminates in suppuration, the abscess often occupies one lateral lobe, though if larger, it appears as if the whole were engaged. Sir B. Brodie says: "The abscess, if left to take its own course, sometimes bursts internally—that is, into the urethra; more frequently it makes its way through the fascia, cellular membrane, and muscles of the perinæum, and bursts through the external skin." The latter part of this opinion I believe to be quite erroneous, and that acute abscess of the prostate opens very rarely in the perinæum; it usually dis-

charges itself either into the urethra or the rectum. At present I wish to call attention to the prostatic abscess opening into the rectum. The symptoms will be sufficiently shown in the following cases:—

Case 1.—Mr. R., ætâ 26, contracted gonorrhœa a year ago. The discharge had ceased, except a little white fluid occasionally, but never yellow, and he was otherwise quite well, when about three weeks since he became affected with pain about the perinæum and anus; at first dull, it gradually became a more insufferable pain, with a feeling as if there was something in the rectum to come away, but he had no difficulty in passing water, and only a little frequency; just at the end of passing water, however, he felt a sharp spasmodic pain at the neck of the bladder. He had been subjected to some treatment without good results, and when I saw him his sufferings were severe, the motion of a cab very painful, and he could not sit straight, but rested on one buttock. He required opening medicine, which he got, and subsequently was ordered blue pill and extract of hyosiamum, with rest in bed, and leeches to the perinæum. The last gave considerable relief, and though the pain recurred the next day, it was never quite so violent. No rigor or fever; pulse a little quicker than natural; tongue slightly furred; but no appetite, and the nights sleepless from the pain. When first I examined him by the rectum I found the prostate considerably enlarged, hard, and very tender; this enlargement and tenderness increased for two days after this examination, but then the pain became rather less, and on passing my finger up the anus I found distinct fluctuation on the left side of the prostate, where the swelling had been greatest. As the suffering was not great, I determined to wait till the next day and then open the abscess by the rectum. Next day I found him quite free from pain, and he could walk about his room without any uneasiness; hitherto walking had always increased his distress. I passed in my finger and felt, as I had anticipated, that the abscess had burst; the tumour much lessened, soft, and flaccid in the centre, where I could distinguish a small ragged opening, round which the prostate was hard and enlarged. He took two purging pills at bed time, and towards morning thought they would act, but he passed nothing but urine; soon after another inclination came on and a small fluid motion came away, and in an hour a second; he did not examine these, but I have little doubt they were the pus of the broken abscess; he then felt easier. Two or three hours after he had a natural motion without pain; he passes water well; two days afterwards I found the prostate rapidly returning to its natural size.

The sufferings in this case were extreme till suppuration was fully established, when they became mitigated. It is curious how little urinary distress there was; all the pain was referred to the perinæum and inside the bowel; the passage of water was very little obstructed. The case occurred in 1864, and I have seen the gentleman frequently since; he has got married, and has not since suffered from any derangement of the prostate.

Case 2.—M., a captain of an American vessel, admitted into the hospital with retention of urine. He had been suffering from the retention for twenty-four hours, and attempts had been repeatedly made to pass an instrument. When I saw him he was in the greatest agony from the impossibility of passing a drop of water, though he was constantly straining to do so; the bladder was distended up to the umbilicus. There was a quantity of blood about the orifice of the urethra, no doubt from the passage having been wounded in the attempts to pass the catheter. His history was that for some time he had experienced a difficulty in passing water, with a diminished stream. Latterly, during a severe passage from America, it had become much worse, till, when he landed at Kingstown, a total retention had ensued. This account looked like that of an ordinary case of stricture. With considerable doubt of success after the attempts that had been made, I proceeded to pass a catheter. The only small silver catheter,

No. 3, that I had at the hospital at the time, was obstructed, but I used it as an exploring instrument, to ascertain the nature of the impediment. There was some soft resistance to the passage of the instrument, which became more decided at the neck of the bladder; I therefore passed my finger through the anus, and found the inside of the rectum very hot, and the prostate enlarged and exquisitely tender, so that he cried out more from this than the passing of the instrument, which being greatly depressed entered the bladder. I thought it best in such a case, having been so far fortunate, to leave the instrument in, rather than try immediately a previous one, in which endeavour I might fail. He was desired to keep the instrument in for an hour. However, at the end of half an hour, he got fidgetty, and withdrew it, when a gush of urine took place, and the bladder was relieved, and afterwards he passed water tolerably well; but he was subject to diarrhoea and irritation about the rectum, with much tenesmus, a constant straining, as if there was something in the rectum to come away. While making an effort of this kind, he felt a sudden gush of liquid from the anus with sudden relief. He had no further trouble, and bid me good-bye a few days after, apparently quite well.

(To be continued.)

CASE OF
RESTORATION OF A PERFORATED AND
COLLAPSED MEMBRANA TYMPANI.

By J. HINTON,

AURAL SURGEON TO GUY'S HOSPITAL.

THE following case is an instance of the facility with which, by the use of very simple means, a cure may be effected in a morbid condition of the ear, which would otherwise, in all probability, be attended not only with more or less of permanent deafness, but with a perpetual liability to periodical attacks of inflammation and supuration of the tympanum.

E. F., æt. 8, was brought to me on the 25th July last, with the following history:—Shortly after being vaccinated over a nævus on the arm, about the age of eighteen months, a discharge had been noticed from the left ear, and had continued with interruptions ever since; there had been none since May, when three or four blisters had been applied, as frequently before. She had had measles last year, not seeming to affect the ear; had not had scarlatina; deafness on the left side had existed from the first; but there had not been pain. The voice was heard on the left side only when distinct and near; watch four inches (heard on the right side at four feet). The left meatus contained a little old discharge, on the removal, of which the membrana tympani was seen to be sunk inwards, in contact or nearly in contact with the inner wall of the tympanum. It was of a glistening white colour and irregular surface, the short process of the malleus strongly projecting, and behind it and a little below was a circular orifice, about a line in diameter, the edges of which were thin and appeared to be closely approximated to the pale and somewhat granular mucous surface behind. The patient could not pass air into the tympanum. The tonsils were large and the faucial mucous membrane swollen. Health good.

Two conditions here demanded remedy—1st, the orifice in the membrane; and 2nd, the alteration in its position. The latter indeed was in all probability the chief cause of the impediment to hearing, inasmuch as perforations of much larger size may exist with little diminution of that function. But the perforation first demanded treatment, because its closure afforded the only conditions under which a successful attempt could be made to bring back the membrane to its right position. This result could be obtained only by the agency of a stream of air introduced

through the Eustachian tube, operating on the membrane from within, and requiring therefore that it should be perfect.

The new and simple procedure introduced by Politzer for inflating the tympanum with air afforded a means of effecting both objects. The plan of operation is the following:—The patient, being seated, takes a small mouthful of water, which he keeps in the mouth until at a signal given by the surgeon he swallows it. The surgeon, standing on his right side, introduces into the nostril of the side to be operated on a small flexible tube, and with his thumb and fingers closes the nostrils over it. This tube may be connected either with an india-rubber bag, or with the surgeon's mouth; in either case he forces into it a sharp stream of air, at the moment when, at the given signal, the patient swallows. The air then rushes up the Eustachian tube (opened by the act of swallowing), and in the great majority of cases, especially in children, overcomes any obstruction that may exist.

In the present case this procedure was employed to effect both the objects desired: first, to induce healing of the orifice; and secondly, to bring forward to its right position the collapsed membrane. The former object was gained by washing out the tympanum persistently by means of a warm solution of zinc sulph. (gr. iv. ad. ʒj.), to which at first gr. i. of hydrochlorate of morphia was added. The meatus was filled with the solution, and air then blown repeatedly through the tympanum in the manner described. By this means the solution was made freely to enter the tympanic cavity, and to coagulate whatever of viscid mucous discharge hung about its crevices. Sometimes a lotion of dilute acetic acid (ʒj. ad. ʒj.) was used in the same way. At the same time the throat was treated with a solution of alum (gr. v. ad. ʒj.), by means of the atomizer, and subsequently by alum applied in powder to the region of the Eustachian tube; and in the course of a few weeks she was able herself to pass air into the tympanum, when the tube was gradually discontinued.

By the middle of October the perforation was healed, the surface being at first of a pink colour, and soft fleshy aspect; but in two or three weeks assuming the thin transparent appearance usual with scars of the membrana tympani.

During this time the hearing did not improve; but after the intermission of a fortnight, to allow time for the new tissue to gain strength, the free inflation of the ear was resumed and carried out twice a week. Under its influence the membrana tympani could be watched gradually recovering from its sunken state, and regaining its natural position; its normal aspect and lustre also in great part returning. At the present time, December 10th, the appearance of the greater part of the membrane is almost that of health; there is, however, still an unnatural prominence of the short process of the malleus and thickening of the membrane around it, at the upper and anterior part also is an oval depression which does not yield to the pressure of the air. The scar of the perforation is just discernible as a darker spot surrounded by a whiter slightly thickened ring. The hearing has also gradually improved; the watch is now heard at thirty inches, and a whisper at ten or twelve feet.

I have reported this case because it shows the effect of very simple appliances, easily at the command of all, in relieving what might have appeared a very untractable lesion. Similar conditions are very frequent in children, and when detected, by examination with the speculum, they may be treated with the greatest probability of a good result. In the chronic and recurrent forms of "otorrhœa" in children, I have found the membrana tympani almost always perforated to a greater or less extent. The accumulation of mucus, more or less puriform in character, within the tympanum, which is exceedingly frequent in childhood, continually leads to rupture and partial destruction of the membrane; the tissues of the remaining portion appear, at the same time, to become soft and wasted, and hence it sinks inwards, yielding probably in

part to the traction of the irritated tympanic muscles. This condition in after-life, when adhesions have formed and become firm, admits of but partial and tedious relief; but taken in an earlier stage, even though after the lapse of several years, and after all signs of acute affection have long ceased, it may yield a result as gratifying to the surgeon as it is beneficial to the patient.

ON TWO CASES OF INJURY OF THE AORTIC VALVES, FROM MUSCULAR EXERTION.

By BALTHAZAR W. FOSTER, M.D., M.R.C.P.LOND.,

PROFESSOR OF CLINICAL MEDICINE IN QUEEN'S COLLEGE, PHYSICIAN TO THE QUEEN'S HOSPITAL AND THE GENERAL DISPENSARY, BIRMINGHAM, &c., &c.

FOR a long time past pathologists have been acquainted with defects of the valvular apparatus of the heart, produced by injury. Since Senac first called attention to the subject, and Corvisart published two cases in which the fleshy columns of the mitral valve were ruptured, several physicians have contributed valuable matter to this branch of cardiac pathology. By no one, however, has the subject been so ably treated as by Dr. Peacock,* to whom, indeed, we owe the greater part of our knowledge of the position of injury among the causes of valvular disease of the heart. The extreme delicacy of the valvular structures, and we may add, in the case of the aortic valves, the very great pressure to which they are subjected under certain forms of muscular effort, might well lead us to conclude that their rupture would be found to be by no means uncommon; actual experience, however, does not at all support such a notion, and injury of the valves during exertion must be ranked as one of the rare causes of cardiac disease. Dr. Peacock very justly remarks that the rupture of diseased valves is by no means so infrequent; but these cases must be distinguished from those in which the injury has occurred to valves not known to be previously diseased. Of this latter class only some seventeen recorded cases are referred to in the Croonian Lectures for 1865, and of these we find that ten were cases of aortic insufficiency, four of rupture of the columns of the mitral valve, and three were examples of a similar accident to the columns of the tricuspid valve. The aortic valves, as might have been expected, are thus shown to be more frequently the seat of this accident than either the mitral or tricuspid; while, as far as I am aware, there is no recorded case of rupture of the pulmonary valves. In this paper I propose to add two more cases of rupture of the aortic valves to the number already recorded. In both cases, the heart symptoms were distinctly traced to a violent muscular effort, and from the history of the patients, there is every reason to suppose that no inadequacy of the valves previously existed. In one case, the post-mortem examination has enabled me to describe the exact nature of the injury, and the condition of the neighbouring structures. In the 2nd case, the man, who is still alive, was of a more advanced age at the time of the accident, and it is quite possible that softening of the valvular structures from atheromatous change, may have preceded the rupture. For when under observation, 10 months afterwards, the sphygmograph told us, in no uncertain manner, that extensive atheroma of the great vessels existed.

Case. 1.†—M. W., aged 33, a discharged soldier, was admitted into the Queen's Hospital, on September 26th, 1866.

History.—The patient had always been in good health until about one and a-half years back, the date of the commencement of his present illness. He had served in an infantry regiment, and for the last six years had been quartered at Gibraltar and other Mediterranean stations. In January, 1865, the accident occurred which caused his discharge, and of which he gave the following account:—One

day, when engaged in the cook-house, he stretched himself across some high coppers in an effort to reach something beyond, and in doing so he felt a sudden and intense pain about the ensiform cartilage. He did not faint or vomit. The pain which was very severe, and which was accompanied by palpitations of the heart, lasted four days, it then passed away, but shortly returned, and he has never since been well. He continued in the service for about twelve months, when he was obliged to go into the Military Hospital, suffering from palpitation, pain in the chest and back, cough, and difficulty of breathing. After five weeks' treatment, he was sent to England, and was discharged in January last; since his discharge he has been unable to work.

State on Admission.—He complained of palpitation of the heart, and a great difficulty of breathing; also of a fixed pain at the ensiform cartilage, and of a sharp pain shooting across the heart, from one armpit to the other, and occasionally running down the arms, particularly on the left side. This pain frequently came on suddenly at night, when he was asleep, and forced him to sit up and struggle for breath. He had a harassing cough, and expectorated mucus, and occasionally blood. The urine was scanty and high coloured, but contained no albumen. There was slight œdema of the legs. Pulse 115, regular, jerky, and visible in the radials. On examination the chest was found to be very resonant all over the lungs. The respiratory murmurs were somewhat harsh, and accompanied by small moist sounds, especially in the lower portions of the lungs posteriorly. The area of cardiac dulness was somewhat increased, extending to the right edge of the sternum. The apex beat was very feeble, and was situated near the upper margin of the 6th rib, one inch and three-quarters vertically below the nipple. On auscultation two murmurs were heard at the base of the heart. The murmur with the systole was somewhat harsh, and was succeeded by a long blowing murmur, which replaced the second sound, and was only terminated by the succeeding 1st sound.

These murmurs were best heard at the "aortic cartilage," and were also audible, especially the systolic one, at the ensiform cartilage and the manubrium sterni. In the carotids a murmur synchronous with the ventricular systole was easily detected, but it was heard but faintly at the back of the chest. At the apex a murmur was audible with the first sound, soft-blowing, and terminated by a prolonged second sound, of a muffled character, almost amounting to a murmur. The systolic sound heard at the apex was well propagated towards the axilla, but was heard faintly posteriorly.

The pulse-trace was taken on both radials and found to present the same characters.

That collected on the right radial is figured below:

Fig. 1.

For some time after his admission the man improved very much, but the œdema of the extremities and the difficulty of breathing from time to time became very urgent; blood reappeared in the sputa, and, in spite of remedies, the bad symptoms steadily increased during the early part of November. Effusion of fluid into the cavities of the chest and abdomen supervened, and the patient died suddenly, while sitting up in bed, on November 24th.

The post-mortem examination was made on November 27th. The legs were very œdematous, and there was evidently fluid in the abdomen. On opening the chest a considerable amount of clear serous fluid was found in the right pleural cavity; some few ounces were noticed in the left pleura. The pericardium also contained 12 oz. of the same. Both lungs were œdematous, and very much congested in the lower portions. Several spots of pulmonary apoplexy were also detected. The liver was of normal size, but somewhat

* Path Trans., Vol. III. *Edinburgh Journal*, Vol. XV., and Croonian Lectures for 1865, "On some of the causes and effects of Valvular Disease of the Heart."—Churchill.

† Reported by Mr. Jas. Sawyer, M.R.C.S.—Clinical Clerk.

congested. The spleen was small and unusually hard. The stomach was very much congested, its mucous membrane presenting a rich blood-colour; but there was no breach of surface. The kidneys were large and healthy. When the heart and thoracic aorta were removed for examination the former weighed 14½ oz. The left ventricle was evidently enlarged, and the aortic valves were incompetent. On opening the cavity of the left ventricle, the left semilunar segment was found to have been torn from its attachment at its junction with the posterior segment, but was still attached about one-fourth of an inch lower down. The injured segment contrasted, by its projection into the ventricle with the others, which were thickened, and rather closely applied to the aorta. It was perforated by two apertures, each about the size of a split pea, while the central part of the valve, extending from the corpus arantii to the attached edge, and separating these apertures, was pierced by smaller rents. The perfect apposition of the valves was therefore impossible, and blood freely regurgitated during life, not only below the edges of the valves but also through the apertures in the injured valve itself. On that part of the wall of the ventricle, immediately below the rents, a band of thickened lining membrane, about half an inch in length, extended downwards; the blood flowing through the ruptured valves impinged on this thickened band.*

The superior curtain of the mitral valve was thickened at its edge on the auricular surface. This thickening was about one-eighth of an inch broad, and uniform, except in one spot, where it was more prominent. There was also some slight roughening round the left auriculo-ventricular aperture, which measured 3.56 inches in circumference.

The cavities of both ventricles were much dilated, and their walls, especially those of the right ventricle, hypertrophied. The valves on the right side were healthy. The lining membrane of the aorta was shrivelled and atheromatous. The aorta was small, and its aperture was only 2.18 inches in circumference. The pulmonary artery was also small.

In this case, whatever doubt there may be as to the extent of the original injury, there can be none, I think, with regard to the cause of the inadequacy of the valves. I am inclined to think myself that, not only was the angle of the valve torn at the time referred to, but that the rents in the fold of the valve also had their origin at the same time, though subsequent inflammation, no doubt, rendered them more extensive. The sounds heard on auscultation in this case find an explanation in the above described conditions. I was due to mitral regurgitation, consequent on the dilated condition of the ventricle, and the thickening of the margin of the superior curtain of the valve. The peculiar prolongation of the second sound, sometimes almost a murmur heard at the apex, and which was at one time thought to be produced at the mitral orifice, was no doubt due to the propagation of the murmur produced by regurgitation through the injured valve. The pulse-trace, Fig. 1, is a striking trace of aortic regurgitation. From its vertical line of ascent, we learned that the murmur of the aortic obstruction was not due to any narrowing of the aortic orifice produced by rigidity of the valves or inflammatory deposits, and the hook-like process, with the sudden, but not considerable, fall of the trace after the summit, told us, that although there was decided regurgitation, it was not very copious.

Case II.—J. N., aged forty-nine, a bricklayer's labourer, presented himself among my out-patients at the Queen's Hospital, on September 21st, 1866, suffering from difficulty of breathing and palpitations of the heart, as well as from diarrhoea, for which he more especially sought relief. He complained that he had been ailing for some ten months, and he referred his illness to an effort made in endeavouring to raise a scaffold pole. He stated that while making this effort, he felt something give way in his chest, and he was seized by a sharp pain in his left side, which compelled him to desist, and made him feel very faint. The pain lasted a week or so, during which time he was confined to

the house, and had palpitation of the heart, and great shortness of breath. Ever since the accident he has been unable, on account of the palpitations, weakness, and dyspnoea, to follow his occupation. He admitted that at one time he had been rather intemperate, but stated that he had always enjoyed good health, having had no illness to mention before the accident. Of late he had lived very regularly. At the time of his admission his tongue was coated with white fur, and he complained of anorexia and occasional vomiting. There was no hepatic or splenic enlargement, but slight pain over the splenic region, which had been felt often during the past few months. Urine healthy.

His chest was well-formed, and the percussion sounds were good over the lungs. Respiratory sounds normal. Towards base of lungs occasional moist sounds were heard. The area of cardiac dulness was not increased; the apex beat was situated between the fifth and sixth ribs, but was very feeble. At the base a soft blowing murmur was heard with the first sound, and lasting throughout the first interval; the second sound was replaced by a slightly rougher murmur, which filled up about half the second interval. Both these murmurs had a subdued flapping character, as if one of the semilunar segments at the mouth of the aorta moved loosely with the blood current. This peculiarity particularly attracted my notice. At the apex the murmurs described above were slightly audible, but were not propagated towards the axilla. They could be heard at the ensiform cartilage, at the manubrium sterni, and over the brachiocephalic artery. The pulsations in the carotid, brachial, and radial arteries were visible. Pulse 60, slow and full.

The pulse-traces were taken, and indicated slight aortic obstruction, with regurgitation. The pulse-trace below

Fig. 2.

was taken with little pressure exerted on the radial artery, and indicated by its line of ascent, aortic obstruction. In the following trace (Fig. 3), when greater pressure was exerted on the vessel, the full force of the pulsa-

Fig. 3.

tion was registered, and the signs of aortic regurgitation were obtained. The increased amplitude of the pulsations in the trace (Fig. 3), the extended summit of each pulsation, the hook-like point not being followed by a sudden fall, render it a marked contrast to Fig. 1, and tell us that the regurgitation was not at all large; that a fair amount of tension existed in the vessels; and that atheroma had affected the larger arterial trunks at the least. The pulse-trace, Fig. 3, is indeed a very typical specimen of the form of the pulse of diminished arterial elasticity, combined with slight insufficiency of the aortic valves. The patient, after a few days' treatment, under which the diarrhoea subsided, ceased to attend the Hospital, so that no opportunity was afforded of verifying a diagnosis which the history of the patient, the sounds heard on auscultation, and the striking character of the pulse-traces rendered very certain.

Several interesting questions, which the study of the above cases suggests, I am unable to discuss in consequence of the length to which this paper has already extended.

4, Old-square, Birmingham.

It is stated that the use of horse flesh as human food is making progress at Nancy. M. Pineau, who has taken up the enterprise, has at present about a dozen horses fattening in his stables.

Hospital Reports.

ST. MARY'S HOSPITAL.

POPLITEAL ANEURISM; LIGATURE OF THE FEMORAL ARTERY.

Under the care of Mr. HAYNES WALTON,

SURGEON TO THE HOSPITAL, AND TO THE CENTRAL LONDON OPHTHALMIC HOSPITAL.

It is right that cases like this be recorded, because it is only by the gathering of facts from a variety of sources that our systematic writers can produce rules sufficiently valuable for the guidance of surgeons.

A patient, a female 24 years of age, was sent to St. Mary's Hospital by a surgeon who had intended to open what he supposed to be an abscess in the ham.

He was mistaken. Some blood flowed from the tumour, and very prudently he sent the woman, who was destitute, to a proper asylum.

Mr. Walton saw her on her arrival, and at once sent her to bed.

This proved to be a very obscure case. Mr. Walton made a very careful examination, and was a long time in coming to a conclusion. The tumour had all the appearance of an enlarged and inflamed bursa. It did not pulsate; it could not be emptied by pressure; and seemed to have a firm attachment to some part. Moreover, the circulation of the foot was not interfered with, and the dorsal artery could be felt in that limb as plainly as on the opposite side. Besides this, the history, which is as follows, was not like that attached to an aneurism. About a fortnight before pain was felt in the ham, and the patient discovered a tumour there; increasing pain induced her to seek medical relief.

The last method of examination pursued by Mr. Walton was this—he compressed the femoral artery while he pressed on the tumour, the effect of which was to partly empty it. Keeping his hand still on the tumour, and remitting the pressure on the femoral artery, he felt the tumour slowly to rise to its former size. This he knew was almost conclusive evidence of the existence of an aneurism, but inconclusive so far as a similar effect might be produced on a soft cancer.

However, he decided for the presence of an aneurism, and proceeded to treat it on the compression system, applying pressure to the femoral artery.

All along there had been a slight oozing from the wound made before the patient was admitted, but it was only enough to mark the piece of lint applied from time to time.

Two days after the pressure had been applied it was evident that it ought to be discontinued, on account of the swelling produced, the pain, excitement, and irritability it caused the patient, and the bleeding to which it seemed to give rise from the tumour. The hæmorrhage was such as to endanger life if not checked. Mr. Walton now tied the femoral artery in the upper third of the thigh, in the presence of a large number of students and others. The operation was very quickly performed in the usual way, there being no complications nor impediments. Everything seemed to progress well for a few days; the patient was relieved from intense pain; and the temperature of the limb was well maintained. The untoward symptom of suppuration in the sac now set in, associated with very considerable depression of the vital power, which rallied but little under full stimuli. The abscess burst, but as the aperture seemed insufficient, Mr. Walton enlarged it and evacuated a great deal of putrid material. On a second occasion he deemed it necessary to prolong the opening in another direction. After this a very great improvement took place in the patient, and there seemed a fair prospect of success. At two o'clock in the day Mr.

Walton said he believed she would recover. Four hours later this poor woman called to the Sister of the Ward, and said—"Sister, something has burst, and I am bleeding." In a few minutes she was dead.

A post-mortem examination proved the existence of a sacculated false aneurism. The cause of the hæmorrhage was evident. There had been no attempt at healthy repair. No fibrinous laminæ had formed in the sac, but merely coagulum, and so soon as this had undergone degeneration and suppurated away, the collateral circulation poured out the blood. There was no time for anything to be done.

MERCER'S HOSPITAL.

MEDICAL WARDS.

CLINICAL REMARKS: WITH CASES.

By WILLIAM MOORE, M.D. Dub., M.R.I.A.,

SENIOR PHYSICIAN TO MERCER'S HOSPITAL; VICE-PRESIDENT OF THE COLLEGE OF PHYSICIANS, AND LECTURER ON THE PRACTICE OF MEDICINE, &c.

"EXOPHTHALMIC GOITRE."

GENTLEMEN,—I think I cannot occupy your time more profitably on the present occasion than by giving you the details of some cases of unusual interest which we have recently had under our observation in this hospital, and the first case I shall bring before you is one of "Exophthalmic Goitre," which has been so carefully reported for us by Dr. H. G. Thompson.

John R., aged 25, a dyer by trade, was admitted into Mercer's Hospital on the 12th of the past month, complaining of a thumping and beating of his heart, accompanied with an occasional sense of suffocation and inability to attend to his ordinary business.

His family history is as follows:—His father is dead; he believes chronic bronchitis was the cause of death; his mother is alive and healthy, whilst all his brothers and sisters died of fever and diseases incidental to early life. The patient has been eight years at his trade, and was always a healthy man up to the occasion of the present attack, which commenced about a year ago in the following manner:—On going to his work on a cold frosty morning he felt chilly and turned into an eating-house to have a cup of coffee; he then went on to his work. When he got to his place of business he became giddy and inclined to faint. This passed off, but again returned, when he remained unconscious for half an hour. On being brought home he was able to tell his wife what occurred, when she immediately concluded that he was poisoned by the coffee. An emetic was given to him, which acted severely; but his wife still remaining dissatisfied another emetic was administered, which, as the patient states, "kept him vomiting from Saturday till Monday."

On admission into this hospital he complained of violent palpitation, which was increased by the least exertion or excitement; his eyesight was so far impaired that he could not define objects a few yards from him, whilst the eyes were prominent, and occasionally felt full and painful on being touched; the pupils were normal; he suffered from giddiness; his lips were livid, and his face slightly swollen; the jugular veins were very much dilated, especially when he was excited by our coming round his bed and on asking him questions, but as he quieted down they subsided. There was visible pulsation of all the deep-seated vessels of the neck, and the tilting of the heart against the walls of the chest was very apparent. The thyroid body was enlarged and pulsated, the left lobe especially, so much so that he was unable to bear his shirt buttoned. The chest generally was clear on percussion, except over the præcordial region, where dulness was well marked, and where distinct frotement was communicated to the hand. The stethoscope revealed

a systolic bruit over the base of the heart and in the vessels of the neck. The pulse, under excitement, could scarcely be reckoned, but when the patient quieted down it ranged about 96. The urine was scanty, specific gravity 1025; contained no albumen.

The treatment we employed was fifteen drops of tincture of digitalis three times a day, and the application of an ointment of digitals over the præcordial region, whilst a small blister was applied over the lowest cervical and upper dorsal spines, the "cilio spinal region." Under this treatment the palpitation and pulsations generally abated, and the circumference of his neck sensibly decreased, whilst his pulse became slower and more regular; in short he left the hospital, as he stated himself, "greatly improved."

Now, this is a type of a class of cases which cannot be said to be of very common occurrence, and which are now generally admitted to be of nervous origin, the vaso-motor system playing the most conspicuous part; and pathology has recently further strengthened this view, inasmuch as Schiff, Bernard, and others, have proved that diseases of the sympathetic system induce in the organs more immediately under their influence, changes which eventuated in atrophy, the texture of the various organs from impaired nutrition, being replaced by fat and cellular tissue; and this condition, in several instances, has recently been found associated with the symptoms, and physical signs I have detailed to you. As regards the prognosis of the disease, my own experience induces me to regard it on the whole as favourable, still the proclivity to relapses cannot be overlooked, which no doubt sooner or later entail organic changes; but, everything considered, the disease is usually amenable to treatment, more especially in females.

Of the remedies I have found most efficacious I should say "digitalis" was the first on the list, in doses of fifteen or twenty drops of the tincture three or four times a day, whilst at the same time it may be applied locally over the region of the heart. Bromide of potassium I have also found useful in half drachm doses, where menstrual irregularity was a complication, and should anæmia co-exist the bromide of iron is indicated. Viewing the disease as vaso-motor or sympathetic in its origin, I should recommend the application of counter irritants over the cilio-spinal region.

(To be Continued.)

LONDON HOSPITAL.

HERNIA PROTRUDING BETWEEN THE FEMORAL ARTERY AND VEIN.

(Under the care of Mr. LITTLE.)

A WOMAN, aged 61, was admitted at nine P.M., January 12th, with a tumour in the groin, and the history that four days ago when lifting a bedstead she strained herself, and had since found a lump in her thigh, which she had never noticed before. Has not been able to keep any food down for three days, nor have the bowels acted, although she has taken "nineteen pennorth" of medicine. There was a tumour the size and shape of a walnut lying below Poupart's ligament, and with its long axis parallel to that band; it was extremely hard and without impulse on coughing. The abdomen was tense, distended, and painful when touched. The patient was weak, cold, her pulse 96 and not easily compressible, and she vomited frequently. Mr. Little, who saw the patient soon after her admission, decided to operate at once. The tumour was freely movable under the skin, and seemed fixed by a constricted neck at the femoral ring. An incision was made over and to the inner side of the femoral ring, and some of its inner fibres divided. On handling the tumour

with the expectation of reducing it, its supposed neck entirely came out of the femoral canal, leaving that space quite free and unoccupied, and the little finger could be pushed up into the abdomen. It now seemed as if the tumour were not a hernia at all, but on exposing it more freely its outer part was seen to terminate in a constricted portion which proceeded from the abdomen under Poupart's ligament, and between the femoral artery and vein. The neck was tightly compressed by the ligament, some fibres of which were divided. The tumour was notwithstanding still reducible, so the sac, which was extremely thin, was opened, and seen to contain a knuckle of small intestine of a dark maroon colour, ecchymosed, and with some lymph on its surface at one spot. A large quantity of nearly clear fluid escaped from the abdomen, and the gut withdrew spontaneously from view. The wound was brought together and bandaged, and two grains of solid opium given. The patient had no more sickness. She took two grains of opium a day for four days to keep her intestines at rest; on the ninth day after the operation the bowels acted naturally without medicine. She recovered with no bad symptom, and was discharged February 20th, when there seemed no disposition to hernia, but a weak truss was applied as a precautionary measure.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

Dr. LYONS'S CLINIQUE.

The several cliniques of this great institution continue to furnish, as ever, a most ample field of observation and research.

In Dr. Lyons's clinique we have recorded the following observations:—

Fever.—Typhus and typhoid fevers have prevailed through the summer and autumn in somewhat lessened numbers, but with well-marked and perfectly typical examples of both diseases, and occasionally of very malignant character. The supervention of the one disease on the other (typhus upon typhoid) has been noticed in a former report. In two instances diphtheria existed as a complication, with fatal result in one case.

Eruptive Fevers.—There would appear to have been a very decided diminution in this class of zymotic diseases, Dr. Lyons's wards having presented but one example of this group of fevers during the past three months. It was an instance of scarlatina in which the arthritic complication became developed, constituting the Dengue of the West Indian observers. The patient made a complete recovery without cardiac or renal engagement.

Use of Chlorate of Quinia.—Further experience of this valuable agent (the introduction of which is due to Dr. Lyons, it will be remembered, and which was first made known to the profession in our pages) has confirmed the views entertained by its inventor. In all the graver forms of typhus, typhoid, scarlatina, small-pox, low phlegmonous inflammations, &c., &c., it has been employed with results of a highly satisfactory character, both in hospital and private cases. It appears to exercise a marked influence in controlling the circulation, sustaining its force, while its rate is diminished. In a case of low typhus with extremely feeble heart and a pulse at 144, the exhibition of a ten-grain dose brought the pulse down from twelve to fifteen beats within an hour after its administration. A case of severe small-pox was treated with it from the outset, in which the pulse never ran above ninety. It is usually administered by Dr. Lyons in a dose of from three to five grains, dissolved by the aid of a like number of drops of perchloric acid.

Cholera.—A total of 238 cases of true cholera have been admitted into this institution since the first outbreak to the present date. The mortality has amounted to 129,

over 50 per cent. Comparing it with other epidemics which he has witnessed at home and abroad, Dr. Lyons remarks on its high mortality by directly fatal issue in the acute stage. Suppression of urine has occurred in a very considerable number of cases, some of which have been successfully treated by active diuretics, the protracted use of the warm bath (thirty minutes). In but an exceedingly small number of instances has true secondary fever been developed, and in no single instance in this epidemic has it occurred to Dr. Lyons to meet with a case fatal by secondary cholera-typhoid, so formidable and so frequent a complication in other epidemics (notably in that amongst the French troops in the East during the Crimean war, in a less proportion amongst the English forces at the same epoch).

Delirium Tremens—Treatment by Capsicum.—Further experience in the use of this somewhat novel remedy has satisfied Dr. Lyons of its value and efficacy. Its success when morphia had entirely failed has been already noted in our pages. Since then it has been employed repeatedly, and with like excellent results. It may, therefore, be confidently recommended as a safe and judicious remedy for general use in this malady. It produces, says Dr. Lyons, a sense of warmth and comfort in the stomach when first taken, allaying the agitation, debility, and cardiac and epigastric anxiety, which are such constant and distressing features of the disease. In from twenty to thirty-grain doses, made up in bolus with honey of roses, it can be taken without inconvenience, and in from one to three hours will be found to produce sleep, from which the patient awakes conscious and convalescent. A recent and very striking case in the Whitworth Hospital, under Dr. Lyons's care, fully confirms these observations.

Syrup of the Phosphates of Iron, Quinine, and Strychnia.—This very excellent therapeutic agent continues to be a favourite remedy in the hands of Dr. Lyons, who reports the most important results of its use on a large scale in private practice. It is applicable to the treatment of a large variety of affections in the child and the adult, the male and the female. It promotes appetite, facilitates digestion, improves the tone of the nervous, vascular, and muscular systems, and may hence be employed with good effect in the debilitated strumous habit in the child, the anæmic and chlorotic states in the female, the low conditions of debilitated frame and broken-down constitution in the adult male, and as an invigorator of cardiac action in those of leuco-phlegmatic temperament, and in cases in which fatty change has commenced to manifest itself in the heart's muscle, after the meridian of life, Dr. Lyons states that he knows of no combination comparable to it. As prepared by his directions, it contains per drachm one grain each of the phosphate of iron and quinia, and one-thirty-second of a grain of the phosphate of strychnia. It may be given in drachm doses to the child of five years old, twice or thrice daily, and commencing with this dose for the adult it may be gradually increased to twice or thrice the quantity named.

Hypodermic Injection.—We have seen this mode of employing remedial agents admirably employed by Dr. Lyons. In the use of the salts of strychnine for the treatment of paralytic lesions, he reports very favourably of its effects. The following instance of its beneficial use has been repeatedly introduced to the notice of his class. The patient was a favourite dorking cock, a bird of very fine figure and plumage. It became, from an unascertainable cause, afflicted with complete paralysis of both legs, and was fast passing into a condition of extreme neurasmus, thickly covered with the peculiar lice which infect this fowl; and it was manifestly fast pining out of existence. About one-twelfth of a grain of the phosphate of strychnine was carefully injected into one of the legs, on a certain day; in three days subsequently a like amount was introduced into the opposite limb. In less than a week the animal completely recovered the use of both limbs; it quickly regained activity, and improved in flesh and form. The bird, we are informed, continues healthy and thriving, after an interval of a couple of months.

Case of Pure uncomplicated Double Bell's Paralysis.—Amongst the most interesting cases which for some weeks has been the theme of comment and study in Dr. Lyons's wards, has been a well marked example of this extremely rare affection.

The patient is a man of fine vigorous form, aged 28, previously healthy, and of by no means generally intemperate habits. About two months since, after a drinking bout, he lay all night on a damp floor, exposed to a severe draught, blowing on his face. When he came to himself the next day he found that the right side of his face was paralysed, and in less than a week subsequently the left side became engaged. He now became seriously alarmed at his condition, and sought admission into hospital. In the state of extreme apprehension and dejection of spirits from which he now suffered, and with the totally expressionless aspect of all his features, the congested eyes and formless pendant and drivelling lips, and imperfect speech, the first impression left on the mind was that produced by a patient labouring under profound centric cerebral lesion with general paralysis; and Dr. Lyons confesses that he was all but inclined to consider the case unfit for admission except to some asylum for incurables. Careful exploration satisfied him, however, of the complete absence of any paralytic lesion than that of the portio-dura at both sides. It was not, however, for some days that this opinion could be fully confirmed. The sense of touch, taste, smell, hearing, and sight were rigidly tested and found to be perfect. There existed the incapacity to close the eyes, while the lower lip hung so powerless that in shaving he had to adopt the expedient of fixing it by the teeth. Mastication and swallowing of food were rendered necessarily difficult and troublesome by the lodgment of parts of the alimentary bolus and fluids in both dental arcades, while all words involving the articulation of the labials were pronounced exceedingly imperfectly. The paralysis of all parts of the face dependent on the seventh pair was complete and extreme. After suitable preparation of the system the patient was placed on the use of nux-vomica; half a grain of the extract subsequently increased to one and a-half grains was given in pill three times a day. Blisters were applied over the root of the pes-anserinus, and dressed with an ointment containing two drachms of nux-vomica to the ounce. In about three weeks the left side of the face, that which was last affected, gradually and finally got well, and perfect power was restored to all its parts. The right side proved much more obstinate and rebellious to treatment. He was repeatedly blistered, hypodermic injection of strychnine, about one-twentieth of a grain was repeatedly employed, and finally electricity was used for a protracted period. A slow, but very decided gradual amendment became perceptible, and every one of the affected muscles re-acquired a certain amount of power, both zygomatics, the levator labii, superioris alæque nasi, corrugator supercilii, orbicularis palpebrarum, and oris being severally capable of being thrown into partial action at will. Amendment steadily progresses, but at this time is not yet fully completed. This case is one of unusual interest from the obscurity of it, and the difficulty of the diagnosis at the outset, the usual contrast in muscular power and expression which so facilitates diagnosis in the ordinary form of one-sided Bell's paralysis being here wanting. Of the rarity of the affection in its double seizure some opinion may be formed, from the fact that no mention is made of it in the works of Watson, Trousseau, or Aitken, and M. Devaine appears to have met no case, except in connection with centric cerebral lesion, and complicated with paralysis of the fifth and other nerves, resulting therefrom.

DEPUTY-INSPECTOR DR. ANDERSON, R.N., who was recently transferred from Malta to Haslar Hospital, has been again transferred to Melville Hospital, Chatham, in consequence of the vacancy caused by the promotion of Dr. Armstrong, R.N., to full inspectorial rank.

NOTICE.

THE MEDICAL PRESS AND CIRCULAR is published simultaneously in London, Dublin, and Edinburgh, every Wednesday morning. Price 5d., Stamped 6d. It will be sent Post Free, direct from the Office, £1 2s. 6d. to Annual Subscribers, or for £1 1s. 8d. if paid in advance.

ADVERTISEMENTS are inserted at the following scale :—

A Page	£4	0	0
A Column	2	5	0
Half Column	1	5	0
Ten Lines and under	0	4	0
Every Line afterwards	0	0	6

☞ A Liberal Discount for a series of insertions.

OFFICES :—

London: 20, King William-street, Strand, W.C.

Dublin: 3, Lincoln-place, Merrion-square.

Edinburgh: Messrs. Maclachlan & Stewart, S. Bridge.

The Medical Press and Circular.

“ SALUS POPULI SUPREMA LEX.”

WEDNESDAY, DECEMBER 19, 1866.

THE EDITOR TO THE PROFESSION.

A COPY of the present number of THE MEDICAL PRESS AND CIRCULAR is forwarded free to every medical man in England, Ireland, and Scotland, as well as to a large number on the Continent of Europe, in America, and the Colonies.

Our object in incurring this large expense is once more to lay our programme before the whole Profession, with a view of showing how far we merit its support. The Journal comes before them as no new venture. THE MEDICAL PRESS had been established more than twenty-six years when its proprietor purchased THE MEDICAL CIRCULAR and amalgamated the two periodicals, at the commencement of the present year. At that time a very large gratuitous issue was distributed by way of apprising the Profession of what had been done, and a special edition for each of the three Kingdoms commenced. The difficulties of so extensive an undertaking were not easily surmounted; but, encouraged by the support of our numerous subscribers, we have lately ventured on a considerable addition to our staff. What has been the effect of this we leave the constant reader to determine, on a comparison of the current volume with the one that preceded it. Casual readers must judge of the change by comparing this number with our gratuitous distribution last January.

Those who have observed any improvement will, no doubt, be gratified by our new announcements. With the coming year we enter on a New Volume—we may, in fact,

say a NEW SERIES—and have made all our arrangements for a still better appearance. Our editorial and literary expenses will be largely supplemented; and in order to do them justice we have invested in several founts of new type, and incurred other liabilities. We therefore feel confident of a larger success.

Mere promises do not furnish that claim to consideration which is due to a fair amount of performance. It is for this reason that we prefer to appeal to what we have done in the last few months as an earnest of what we hope to accomplish. It can scarcely be denied that there is ample scope for a well conducted medical journal. With our special edition for each of the three Kingdoms, we occupy a position which is altogether undeniable. It has been stated over and over again that the Profession wants a thoroughly respectable, representative organ, conducted with honesty, independence and spirit. This want it is our purpose to supply. Those who may be familiar with class journalism well know the difficulties that lie before us, and those who desire to possess an independent organ will not be slow to offer us their support.

Only the other day, in a conversation with one of our most distinguished hospital surgeons, we were reminded that if we could afford to be “respectable” a bright future was before us. After investigating all the meaning he attached to the word, we declared that we were endeavouring to carry out his idea. He told us, what we well knew, that too much of medical journalism was conducted in a trading spirit, and that to be thoroughly respectable would probably entail temporary, pecuniary loss. This we are prepared to incur, and, in order to sustain the character of THE MEDICAL PRESS AND CIRCULAR, we have already made sacrifices that we by no means regret.

To descend from generals to particulars: As already stated, in order to raise the tone of the journal we have considerably increased our staff. An additional corps of experienced writers has been obtained. We have secured the services of gentlemen accustomed to write for the literary and scientific periodicals—contributors to the daily, weekly, monthly, and quarterly press. Thus we shall be able to offer our readers a greater variety of original matter, and this clothed in all the attractions of literary grace.

In our Leading Columns we shall, as warmly as for the last twenty-seven years, champion the rights of our profession, and uphold the claims of its members to the respect, confidence, and gratitude of the public.

Our Original Communications will probably yield to those of no other journal in interest and practical utility. Promises of support from many of the leading Hospital Physicians and Surgeons of London, Dublin, and Edinburgh offer a sufficient guarantee of the value of this department. Not a few of the subjects originally thought out in such papers will doubtless become classical, while clinical lectures from such sources will be

worthy of the attentive study of both students and practitioners.

In the department of Hospital Reports we shall continue to record a number of the more interesting cases that are seen in the wards of the great hospitals of the three capitals. To these we shall at all times be pleased to add such cases as may be sent us from provincial hospitals.

Perhaps this is the most appropriate place to state that we are ready to publish instructive cases, with or without comments, from private or parochial practitioners. We are well aware how large an amount of valuable information is always running to waste, not only in our towns, but in the country districts—how many of our country brethren perform the capital operations, and meet with other cases that are of equal interest to those selected from the metropolitan hospitals. We invite them to record their experience in our pages, or at least to place the rough notes they may have preserved at the disposal of the Editor of our Hospital Reports.

We may here pause to call attention to a somewhat new feature in our journal: Imbued with the hope of making it as useful as possible, we have worked hard to render it thoroughly practical. To the Hospital Reports and Original Communications we have recently added another kind of special reports. In these the material is so grouped as to illustrate points of interest more fully than the isolated cases of ordinary Hospital Reports can possibly do. The condensed Clinical Address in our present number by Dr. CLARK is partially of this nature; a more characteristic specimen is the Special Report on the Treatment of Cholera by Injections into the Veins, which has appeared in our columns during the last few weeks, and created so much interest. Other finished Clinical Reports of this kind, specially prepared for THE MEDICAL PRESS AND CIRCULAR by experienced writers, will be published from time to time, and cannot fail to prove one of the most attractive features introduced into medical journalism.

As to Medical Literature, how many complaints have been made that the reviews and notices of books in most medical journals are unsatisfactory in the extreme! At an assembly of the writers for one of the most critical of our literary and political journals this was remarked to us a few weeks ago, and we were assured that criticisms in medical periodicals were generally believed to be governed by the most execrable motives. It was broadly asserted that "medical literature is divisible into two classes—1st., the organ of a clique or a society; 2nd, the mere publishers' or booksellers' hack." On the part of THE MEDICAL PRESS AND CIRCULAR we proudly repudiated the notion, and explained our position. Our connections in England, Ireland, and Scotland afford us the opportunity of allowing one country to pronounce on the productions of the other. Rival schools and hostile cliques there may be in each capi-

tal, but these are strictly local, and it is easy for us to secure fair criticism for writers by forwarding their books for review to one of the other cities, where the prejudices of their own locality cannot obtain.

Moreover, we number on our staff literary and scientific gentlemen whose opinions on books must be of value, apart from mere professional status, and it will be our endeavour in the Reviews—a department in which we hope to maintain our reputation for just discrimination—to make them infinitely more worthy attention than heretofore. Nor do we purpose to confine our criticism to strictly professional works; every book that comes before us, and which we think may interest our subscribers, will receive a certain amount of attention at our hands.

Our columns are open to Correspondence on all subjects interesting to the Profession at large, and no letter will be rejected on account of the opinion it may express, each correspondent being of course answerable for his own writing. Many complaints have reached us respecting the impossibility of obtaining fair play by the insertion of letters in certain journals. We can only say that in THE MEDICAL PRESS AND CIRCULAR the Profession possesses an open arena for all comers—"a fair field and no favour" to either men or their opinions.

In the Foreign Department THE MEDICAL PRESS has long been pre-eminent—a position we are determined to maintain, as we believe it is of the utmost importance that the Profession should be kept *au courant* with what is doing abroad as well as at home, and the busy practitioner spared the expense of many journals, and the toil of reading foreign languages.

If any proof were needed of the value of the Foreign Department of THE MEDICAL PRESS AND CIRCULAR, we should not hesitate to omit all reference to French, German, and other more generally known languages (which we have, nevertheless, not neglected), and point to translations from the Swedish, Danish, &c., with which that learned physician and Scandinavian scholar, Dr. W. D. MOORE, has frequently adorned our pages, and whose invaluable communications will continue to occupy an important place.

We have already gone so lengthily into our intentions that many minor matters can receive no mention. We must, however, beg that the reader will accept this number as a token of our fixed unalterable determination to make THE MEDICAL PRESS AND CIRCULAR all he could desire. To any suggestions offered we shall always be open. Indeed, we invite every kind of co-operation in our effort to raise medical journalism to the level to which it is justly entitled, and to establish a periodical worthy to represent the noble and God-like Art of Healing in all its various branches, in its many aspects to its several members, and in all its changing relations to Science, Literature, and the Arts, as well as to the great Commonwealth to which we belong.

ON THE PREVENTION AND TREATMENT OF CHOLERA.

ABOUT a year ago (January 10th, 1866), we warned the Profession that, according to all previous experience, an epidemic of cholera was impending; and we may now add that, according to past experience, we are not yet nearly done with the epidemic which now rages. It is of importance, therefore, to take stock of our experience, and ascertain what we have learned as to the prevention and treatment of cholera. In our former article we summarised the leading articles of our faith in regard to these particulars by stating that, with a bottle of Condy in every house and a box of opium pills in every man's pocket, we might bid defiance to the cholera, and our late experience has but confirmed the doctrine that cleanliness and disinfection are our surest safeguards, and large, full, and early doses of opium (in the stage of premonitory diarrhœa) a safe and almost an unfailing specific. To insure a thorough removal of all noxious materials, it is necessary to have a careful inspection of each district by a party free from local interests and prejudices; without that the work will be only half done, if done at all. We are acquainted with a country district which suffered in all preceding epidemics; the local inspector gave a most flattering and favourable report of the sanitary condition of the district; the local Board of Health, however, aware that prevention is better than cure, thought right to request a gentleman wholly unconnected with the district to inspect it for them. The result was, that the local inspector's own premises were found to be in a most unsatisfactory condition, while no less than *forty cart loads* of filth were taken out of about two or three hundred yards of a burn, running, partially closed in, in front of one street of the chief village, and acting as its common sewer. The sanitary state of the district was made really secure under efficient inspection, and the consequence is, that it has entirely escaped; one case, the infection of which was probably imported, is all that has occurred within it. The man died, but his bedding was burned, the house disinfected, and it spread no further there. The father of this man, however, came from Fife to attend his son's funeral, and he returned to die of cholera in his own village, and in it and the two or three neighbouring villages, the sanitary state of which was wholly neglected, nearly three hundred deaths have occurred within the last two or three weeks. Again, one village in a closely-adjointing district suffered severely during the last epidemic. They contented themselves with the inspection of local officers. Cholera broke out, and in three days carried off fifteen of its inhabitants. The sanitary condition of this village was found to be most defective, and the drinking water contaminated by nitrates.

These facts, as well as many others which we have not space to quote, efficiently prove that a sound sanitary condition is an effectual safeguard, and that the best

mode of preparing for cholera is not to dig graves, as the French Maire did when warned by his Prefect that cholera was approaching, but to insure by careful inspection rigid cleanliness of houses, persons, and drains, as well as an ample supply of pure water for cooking and drinking. The history of the present epidemic in Edinburgh, when it comes to be written, will show how much we owe to our ample supply of pure water, as well as to the efficient inspection and active preventive and stamping-out measures which have been so ably carried out by that energetic Medical Officer of Health, Dr. Littlejohn, to whom the community owe a debt of gratitude, the amount of which can, unfortunately, be only properly estimated by the initiated members of the Medical Profession.

In regard to the treatment of cholera, the almost universal testimony of all who have had any practical acquaintance with this disease is in favour of its being readily and easily checked in the stage of premonitory diarrhœa by large and full doses of opium, sufficiently frequently repeated till all rumbling has ceased. After the disease has passed into the stage of collapse, however, we find the utmost discrepancy prevailing as to what is to be considered as the most efficient remedy, there being hardly a drug in the Pharmacopœia which has not its advocates and its list of cures. After a certain lapse of time, indeed, under all systems of treatment, a certain amount of reaction sets in, and the patient either recovers, sinks into coma, or dies exhausted; and it is probable that, *cæteris paribus*, he has the best chance of recovery when there is no chance of the healthy natural process of convalescence being interrupted by the secondary absorption (as it may be termed) of a mass of drugs poured into the system during collapse, when absorption is more or less in abeyance, and which, if active at all, must act more or less injuriously when the circumstances which called for their employment have passed or are passing away.

The treatment of cholera may be included under three distinct methods—that by eliminants, including all purgatives; that by salines; and that by neurotics. The theory of elimination is based upon the fact that the most sudden and severe cases of cholera are those unattended by vomiting and purging. We acknowledge the truth of this fact, but we think it may be otherwise more satisfactorily explained, and we say that if elimination be a true remedy for the fully developed disease, it ought, *a fortiori*, to be a still more efficient remedy for it in its nascent stage, and ought, therefore, to cut short, *tuto, cito, et jucunde*, all choleraic and premonitory diarrhœa. All practical experience, however, backed by copious statistics which we have not room to quote, is opposed to this doctrine. The elimination theory may, then, be put summarily out of court, and we only add that it is inconsistent with our practical experience of all diseases of the same class as cholera (the zymotic), and at variance with the doctrine of zymosis itself; for, as we may almost empty a vat of its fermenting contents

without checking the process of fermentation in what remains, so we may drain the body of its fluids, but by so doing we do not check the zymotic process in what is left, though we manifestly lessen the powers of the organism to complete this process, and diminish its chance of surviving its completion.

The treatment of cholera by salines is a most wonderful episode in its history, and its effects are most remarkable, whether we consider the fact that the saline constituents of the blood are not diminished, or the extraordinary results attained alike by most copious injections of saline fluids into the veins, or by comparatively trifling injections into the cellular tissues. In former days the infusion of many pounds of saline fluids into the veins often brought back apparently the most hopeless cases from the gates of death; in more recent times the injection of a single ounce of a saturated solution of chlorate of potass has been attended with a similar result; in both cases the cramps cease, the colour returns, and the heat is at least partially restored, and yet the ultimate success has not been such as to warrant us in concluding that salines are a cure for cholera. In recent times the saline remedy which has been most largely employed with the most sanguine expectations as to its probable efficacy has been the bromide of potassium. Like all other salines, it has relieved the cramps, restored the colour, and the temperature has also at least partially returned, the urine being secreted more or less copiously, but remaining of a low specific gravity, and yet the ultimate results obtained have not been such as to warrant us in saying that the bromide of potassium is a cure for cholera, while the large doses in which it has to be administered, three grains every hour or half hour, have awakened grave doubts in the minds of many whether, if it be—as it seems to be—a powerful sedative to the nervous system, some, at least, of the many cases of coma following its use may not have owed their severity, if not their occurrence, to the absorption of the large quantity of this drug.

The last mode of treatment—that by neurotics, including opium—is that which probably has at the present time the greatest number of adherents and can boast of the largest number of cures, and it is to that class of remedies we would desire to direct the attention of our professional brethren as that in which we are most likely to find a solution to this mystery—a cure for cholera. Almost all medical men, we believe, who have reflected at all upon the nature of cholera are agreed that it is a neurosis, the fatality of which, though complicated and increased by serous discharges from the stomach and intestines, is not solely caused by those, but is often most sudden and remarkable when they are almost or entirely absent. In such cases the symptoms all point to a complete cessation of all the vital processes of nutrition and secretion, the result being internal congestion, with paleness or blueness of the external surface and depression of the vital

heat, accompanied by cramps. What is the nature of the neurosis which causes these symptoms, and how may it be remedied? The researches of BROWN-SEQUARD have taught us that cramps, spasms, and convulsive movements are produced by the circulation in the spinal cord of venous blood, the spasm, diarrhoea, morientium, and convulsions of those dying asphyxiated affording us the most common examples of this, to this class the cramps of cholera unquestionably belong, and we may set them aside as a necessary but subsidiary phenomenon. The other phenomena whose explanation we seek may all be comprehensively included under the common term cessation of the nutritive acts; but these we know are not the result of any influence emanating from the nervous system, but are produced solely by the influence of certain specific stimuli upon certain specific susceptibilities, which the nervous system is created for the purpose of co-ordinating in accordance with the requirements of our complex organism. When these nutritive acts cease, therefore, it is not because the nervous system ceases to supply nervous influence, but because it is stupified, benumbed, as it were, by the poison of cholera, and so rendered incapable of performing its part in that wonderfully complex machine, our organism; and as we cannot eliminate the poison of cholera artificially any more than we can that of any other of the class of zymotic diseases, but must content ourselves with obviating the tendency to death till it is eliminated by natural processes, so in this case our greatest hope would seem to lie in the employment of such neurotics as tend to maintain and increase the vital activity of the nervous system, and especially in such as increase its sensitiveness to stimulant impressions, and it is in this direction we believe that the most hopeful results are to be expected. The researches of BROWN-SEQUARD, BONNEFIN, and others, have taught us that morphia and opium greatly increase the reflex activity of the cerebro-spinal system, and opium, we know, has proved by far the most useful remedy in cholera, particularly in its early stage; to this its astringent action has probably contributed not a little by retaining within the system the vital act, while its narcotic action has been its chief drawback, as tending to complicate and even increase many of the most serious symptoms. But there is another remedy which possesses all the beneficial neurotic actions of opium without any of its injurious tendencies, and that is strychnine, recommended long ago by M. ABVILLE, who cured ten out of twenty-four severe cases by its means, and who states that the development of its physiological symptoms was always attended by removal of the symptoms of collapse. It has been altogether lost sight of in recent times. Quite lately, however, it has been employed with marked success in Japan, by Assistant-Surgeon W. HEUSMAN, and also by Dr. BALFOUR at Leven. The latter gentleman states, that its

use is followed by speedy cessation of the cramps, by mitigation of the purging and vomiting, and by return of the pulse to the wrist, even though it may have been absent for hours, as well as by copious secretions of urine.

The type of the disease at Leven was of a most severe character, attended by comparatively little vomiting and purging, the cramps not severe, but the patient speedily sinking into complete collapse. Nevertheless, of twenty-four patients thus treated, nine recovered, while of those who died, three were from 70 to 80 years of age; two above 60; one had long-standing disease of the uterus and chest; and others were greatly deficient in stamina, while all those who recovered were completely collapsed, and several had no pulse at the wrist for three or four hours. The treatment adopted was one drachm of laudanum at first, and if the disease went on one-quarter of a grain of strychnine in solution, at first followed by one-eighth of a grain every hour and a half or two hours till the physiological symptoms (twitching of the muscles) were manifested, when recovery set in. The previous use of opium does not interfere with the action of the strychnine; but, on the contrary, from the correlation of their actions on the spinal system, aids it. Even though our short notice may not have made out a conclusive case for the use of strychnine, we think that the history of the disease and of its treatment warrants us in pointing to the class of neurotics as that in which we are most likely to find a cure for cholera, and we entertain great hopes that a more extended trial will only confirm the present apparent success of strychnine; meanwhile, it certainly saves us from the reproach of having no remedy we can safely employ during the stage of collapse.

CHOLERA.

THE solitary death reported in our last number as having taken place since the issue of the Registrar-General's returns for the week previous, of course appears in his return for the following week, which ended on Saturday the 8th inst. We are glad, however, to add that it forms the only unit for that week, which was the 49th of the year. The death in question was that of a labourer's child, two and a half years old, and took place at Poplar. During the last five weeks the deaths from cholera have declined as follows: 67, 32, 8, 3, and 1.

The total mortality of London during the week was nevertheless above the estimated average by 59, the deaths registered having numbered 1584. The excess, is however, accounted for by bronchitis, which at this season of the year always increases in fatality.

In the supplement to the weekly returns published last Wednesday, there are many interesting details respecting the late epidemic, of which we present our readers with the most important. It appears, first of all, that the deaths by cholera in each district to every 10,000 inhabitants were as follow:—In St. George, Hanover-square, 2 in 10,000 died of cholera; Chelsea, 4; Westminster, 6; Marylebone, 3; Kensington, 4; all on the

north side of the Thames, and supplied with water by the Grand Junction, the Chelsea, and the West Middlesex Companies.

The following districts on the south side of the river were supplied by the Southwark and by the Lambeth Companies, and the deaths by cholera to 10,000 inhabitants were in Newington, 3; St. George, Southwark, 7; Wandsworth, 5; Camberwell, 6; Rotherhithe, 9; Lambeth, 7; St. Olave, 9; Bermondsey, 6; St. Saviour, 7.

The New River, taking about 82 per cent. of its water from the river Lea, supplies St. Martin-in-the-Fields, where the deaths were 4 by cholera in 10,000 inhabitants; in the City of London, 5; West London, a part of the City without the walls, 12; Strand, 7; Islington, 4; Holborn, 6; St. Luke, 16; St. Giles, 10; Clerkenwell, 11. In Pancras, chiefly supplied by the New River, the deaths were 6; St. James's (Westminster), 4; Hampstead, 1.

In these, as well as in other instances, it will be observed that the Registrar-General continues to place beside the figures showing the mortality a statement respecting the water supply, and as we have previously remarked upon all the facts and theories in relation thereto, it will not be unfair to again place these returns before our readers in the same juxtaposition, merely premising that we doubt very much whether the East London Company "will now be willing to relate all the circumstances," which the Registrar-General seems to anticipate. We shall therefore give such facts as we find in the supplement.

The East London Company draws all its water from the river Lea, but it has pumps at two different stations, the one at Lea-bridge, and the other two miles below, at Old Ford, where it has a small covered reservoir and two open reservoirs in "dangerous proximity" to the Lea, at a point where that tidal river is full of foul sewage; the deaths here were at a very different rate—namely, 63 in Bethnal-green, 65 in Mile-end Old-town, 93 in St. George's-in-the-East, 85 in Poplar, 78 in Whitechapel, 111 in Stepney. There are two sub-districts on the east side of the Lea, also supplied by the East London Company, and the deaths were at the same rate as on the west side.

In three districts supplied partly by the New River, and partly by the East London Company, the deaths were in intermediate proportions—namely, 13 in Shoreditch, 12 in Hackney, 16 in East London district, which is a part of the City of London without the walls.

The evidence of the value of improved water supply afforded by the experience of the South London districts in 1849 and 1854, has been so often commented upon that we are tempted to complete it by extracting the figures relating to those years compared with the present. In 1849 both the Southwark and Lambeth Companies supplied the foul water of the Thames, loaded with sewage, to their districts. The Lambeth Company got purer water from the Thames above Teddington Lock before 1854, but the Southwark Company only succeeded in supplying the purer water after the year 1854. In the present year both companies have supplied this better, if not perfectly pure water, of the Thames; while the shallow pumps have been dried up by the drains—with the following remarkable results:—The deaths by cholera to 10,000 inhabitants of South London were 120 in the year 1849, 87 in 1854, and 8 in the year 1866. From cholera and diarrhoea the deaths out of the same numbers living were 142, and 104, and 15! As the water improved the deaths declined to this marvellous extent. Similar, if less striking, evidence

of the effects of pure and impure waters is supplied by the experience of the other London companies.

To the above facts it is necessary to add the following, in reference to the latest outbreak at Woolwich:—

In Lewisham, including Plumstead and Charlton, the deaths by cholera were 6 in 10,000 inhabitants; in Greenwich, Deptford, and Woolwich, 20; both these districts are supplied by the Kent Company in conjunction with the Lambeth and the Southwark Companies.

A most gratifying and conclusive proof of the good effects of improved water supply is afforded by the experience of the South London districts, which were undrained and were supplied with the foul sewage water of the Thames by the Southwark and Lambeth Companies in 1849.

Professor Frankland has analysed the water of the East London Company, taken at the Stamford hill reservoir on the 8th of November, with the following results:—The solid matter in 100,000 parts, 31.30; organic and other volatile matter included in the preceding, 1.28; oxygen required for oxydation of organic matter, .0467; degrees of hardness, 21.7.

From the other figures, in relation to the public health during the week, we select the following:—

The annual rate of mortality in the week was 27 per 1000 in London, 29 in Edinburgh, and 29 in Dublin; 26 in Bristol, 25 in Birmingham, 31 in Liverpool, 29 in Manchester, 27 in Salford, 29 in Sheffield, 36 in Leeds, 30 in Hull, 35 in Newcastle-upon-Tyne, and 32 in Glasgow.

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29.682in. The mean temperature of the air in the week was 46.9 deg., which is 4.8 above the average of the same week in 50 years (as determined by Mr. Glaisher). The mean of the highest temperatures of the water of the Thames was 44.5 deg.; that of the lowest was 41.4 deg. The difference between the mean dew-point temperature and air temperature was 3.5 deg. The mean degree of humidity of the air was 88, complete saturation being represented by 100. Rain fell to the amount of 0.99in. The general direction of the wind was south-west. According to a return furnished by the engineer of the Metropolitan Board of Works, the average daily quantity of sewage pumped into the river Thames at the southern outfall works, Crossness, was 222,840 cubic metres.

SCOTLAND.

It is satisfactory to learn that the epidemic may also be stated to have ceased in the North. Up to the time we write, a fortnight has elapsed without fresh attacks in Edinburgh. Since the outbreak in that capital only about 100 have occurred, with a mortality of a little over 50. The last convalescents having been discharged, the Cholera Hospital has been closed. No prior epidemic has ever proved so mild; and considering that no quarter of the city was exempt from the influence, there is abundant cause to be grateful at so speedy a disappearance of the disease.

METHIL-HILL, Fifeshire.—Three more cases were reported last week, making a total of 76 in a population not exceeding 400, and by some estimated at only 300. The village is still deserted; more than half the houses remaining empty, the fugitives fearing to return. In the neighbouring villages, to which the disease had spread, it may be said to have disappeared. It is stated that in some of

these it is proposed to re-open one or two of the wells which were closed at the period of greatest alarm. We sincerely trust that such a step will not be rashly taken; a little temporary inconvenience would be a thousand times better than a renewed outbreak.

Notes on Current Topics.

TELEGRAPHING FOR THE DOCTOR.

It is now proposed that the Government should purchase and work the telegraphic lines of the United Kingdom, and a carefully drawn up scheme for this purpose has already received the approval of the Ministry. Should this be carried out we believe a uniform charge for any distance will at once be adopted, and the tariff, now higher than the Continental and American lines, considerably reduced. This will make the wires a supplement to the Post Office, and if only managed as well as that department has been, we see no reason why the scheme should not yield a handsome profit. The objections entertained by many to Government management may well be put aside in consideration of the convenience that would result to the public, and we desire to place on record our conviction that it is impossible to carry on the telegraphic correspondence of the country in a worse manner than the companies have hitherto done. The continual delays and miscarriages that occur have compelled us to request our patients to trust as little as possible to a telegraphic despatch. There are few consulting practitioners in London who have not had reason at one time or other to complain. Some time since the writer was summoned to the south coast by a telegram addressed to him at a house where he was known to be visiting, situated within a few doors of a suburban telegraph office. The message went to the central office in the city, and was thence forwarded not to the branch office, but by a boy who walked the distance in two hours and a half, which omnibuses running every ten minutes accomplish in half an hour. A second and third delay occurred in the same manner during the next ten days, and this although it was pointed out how easy it would be to send the message to the suburban station.

The same individual, whose practice, by-the-by, is none of the largest, has found it safer to send a packet by train to towns within an hour's ride of the metropolis than to trust to a telegram. One more example:—A short time ago a letter was received by the writer from one of the midland counties one Saturday evening, requesting an answer by telegraph, to fix the time for a consultation on Monday. The letter was duly forwarded to his residence in the suburbs. But it being past seven o'clock, all the telegraph offices near were closed.

The next day, being Sunday, nearly all the offices in London were also closed; but on application at a central office the message was accepted at double the usual rate. This was considered fair enough, but the worst feature remains to be told. This message, for which extra charge was duly paid, did not reach its destination till next morning, because the office at the town to which it was sent was closed on Sunday. This instance is cited as the most recent, although others could be given in which an urgent message, calling a physician into the country, has been

sent on Saturday evening, and not delivered till Monday morning. Two inferences from these facts seem to us fair:—1. The proposed purchase by the Government is likely to prove beneficial rather than otherwise. 2. Until some amelioration takes place beware of telegraphing for the doctor, especially on Saturday.

ABSOLON V. STATHAM.

ON Tuesday, the 11th instant, an influential meeting of the Medical and Dental Professions was held in the Literary and Scientific Institution, Edward's-street, Portman-square, for the purpose of expressing sympathy with the defendant in this case, on which we have already commented at length. Sir William Fergusson, ever ready to serve the profession to which he belongs, occupied the chair, and in the course of an interesting speech alluded to the ridiculous notions entertained by the public respecting the administration of anæsthetics, stating that it was due to Dr. Snow that the late Lord Campbell refrained from introducing a bill into Parliament, based upon the erroneous hypothesis that a person could be rendered insensible in the public thoroughfares by merely waving before his face a handkerchief on which a few drops of chloroform had been placed.

The Committee, which was formed after the trial submitted a report concluding that it was inexpedient to take steps for organising a defence fund, or to address any statement to the public. Moreover, as no new trial can be moved for, and as Mr. Statham, who is happily in better circumstances than many of his brethren, has very properly declined to accept a pecuniary testimonial, it was recommended that a resolution should be adopted expressing the warmest sympathy with Mr. Statham in the unjust and cruel persecution he has been subjected to, and unabated confidence in his practical skill and professional integrity and honour; and that in the case about which the prosecution arose, his treatment was sound, skilful, humane, and beyond reproach. We need hardly say that this report was adopted with enthusiasm. The meeting passed the resolution, and determined to have it engrossed on vellum, signed by the chairman and others, and presented to Mr. Statham. We have already expressed our sympathy with Mr. Statham, and have only therefore to add our congratulations to him upon the manner in which the whole profession has stood by him.

PAPERS ON DERMATOLOGY.

No. V. PRURIGO.

By T. W. BELCHER, M.A., M.D. Dub.,

FELLOW, CENSOR, AND EXAMINER, KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND; PHYSICIAN TO THE DUBLIN DISPENSARY FOR SKIN DISEASES, &c.

(Continued from 5th December, 1866, page 574.)

IN the four preceding papers I gave cases of SYCOISIS, ECZEMA, HERPES, and PORRIGO, respectively; and appended practical remarks regarding the symptoms, varieties, diagnosis, prognosis, pathology, and treatment of these diseases. In this paper I proceed to give a case of prurigo senilis, and to make observations on the varieties of prurigo:—

V. H., aged 60, unmarried, by occupation a clerk, came to the Dispensary for Skin Diseases on the 25th of August,

1865. For a considerable time previous to his first appearance at the Dispensary he had been affected with prurigo senilis, the ordinary symptoms of which I need not here describe, as they were complicated with others at the time I first saw him. He had then intolerable itching all over the body; no distinct papulæ could be seen, but they were represented by small blackish crusts, respecting which it would be hard to say whether they were the result of the papulæ or of the scratching. This man had, however, the chief peculiarity of all cases of prurigo senilis—the presence of innumerable pediculi all over the body. No efforts of his own sufficed to rid him of these troublesome attendants; and his sufferings, when warm in bed at night, he described as intolerable.

At first he was directed to take hot baths thrice weekly; and also to use a lotion composed of a solution of corrosive sublimate with ammoniated mercury; along with diluted ointment of nitrate of mercury. At the outset this mode of treatment procured some relief, and seemed to diminish the pediculi in numbers. On the 12th of September chloroform was added to the lotion; on the 25th black-wash was substituted for it; and on the 29th a borax and hydrocyanic acid lotion was substituted for the black-wash. On the 10th of October he began to apply a strong solution of soft soap; on the 17th he began to take sulphur vapour baths twice weekly, and to rub methylated spirit into the skin. On the 20th he got an ointment of borax and chloroform, and on the 27th he was directed to use a lotion composed of a solution of borax with creasote and hydrocyanic acid. This lotion, with the sulphur vapour baths, was continued with little good effect up to the 8th of December, when he began to use a lotion consisting of spirit of turpentine, methylated spirit, creasote, chloroform, and the yolks of eggs. On the 12th he began to take a mixture containing Fowler's solution and tincture of bark, three minims of the arsenical preparation being absorbed thrice daily on the principle advocated in my previous papers.

The arsenic *per se* soon disagreed with him, so on the 9th of January he got instead of it a quinine mixture, containing the same proportion of Fowler's solution as before. This he used for a long time with one of the varying lotions already described, and with simple hot-baths, which he sometimes took at 100° F.

On the 20th of March, 1866, he began to use a lotion containing chloroform and carbonate of potass; and on the 27th he stopped the arsenic and quinine, substituting for it a mixture containing liquor strychniæ, five minims of which he took thrice daily in that form for a considerable time. The dose was subsequently raised to seven minims.

On the 27th of April, 1866, he resumed the arsenic; and here I may observe that his disease was occasionally improved more or less, but notwithstanding every effort it always recurred at irregular intervals with its original virulence. On one night he would feel comfortable, while on the following he would feel tormented.

On the 11th of May the arsenic was given up, for the reason before stated, and tincture of the perchloride of iron was substituted for it for about a week, when arsenic again had the pre-eminence.

On the 22nd of May he for the first time admitted that he was really better, and he was desired to use a diluted mercurial and glycerine ointment every night, and a hot bath immediately after it.

On the 8th of June the itching had in great part disappeared, but some of the pediculi remaining, I prescribed for him an ointment consisting of 120 grains of pulvis staphisagriæ to 360 grains of axungia. By the use of this and an occasional aperient he gradually got better and better, and finally ceased his attendance, being to all appearance cured, on the 24th of July, 1866. He has not since returned; and I may remark that he was eleven months under treatment.

If any one will read through the great variety of treatment advised for this affection in books, he will at once

expect that prurigo senilis must be a most intractable disease; and so it is.

The number of cases of prurigo senilis is very large as compared with the number of cases of other skin affections; and, so far as my experience goes, it is the most intractable of any of the acute cutaneous diseases.

In this case almost every conceivable plan of treatment was tried; and, though successful in the end, it could not be said that the cure was due to any one of them. I have never had a case so inveterate as this one, but if I should meet with such another, I would feel inclined to try arsenic first, and then strychnia; and as regards local applications, I should prefer hot baths, chloroform, and Stavesacre.

The preceding case is a fair type of a severe kind of prurigo senilis; and here I may make a few observations on the other variety, prurigo vulgaris, referring the reader for more minute details to my edition of Neligan, p. 334. Prurigo vulgaris may be either mild or severe. In the former case it is termed prurigo mitis; in the latter prurigo formicans. The mild variety is characterised by a cutaneous eruption of scattered papulæ about the size of millet-seeds. These papulæ are colourless, often invisible save by the aid of a magnifying-glass; and, generally, they may be detected by passing the finger over the skin. There is no accompanying redness, inflammation, or undue heat; the itching, or pruritus, is at first not severe: the patient scratches the affected parts, tears the papulæ, and thus forms minute blackish crusts on them. In this condition the physician generally first sees the patient.

In prurigo formicans papulæ are not invariably present, though they generally appear at some stage of the disease; and when they do so appear they are sometimes larger than in the mild form. The aggravated character of the itching is, however, the chief characteristic of this variety; and hence its name, formicans, so termed because of the comparison of the itching sensations to those produced by ants stinging the surface. The itching is seldom constant, but it recurs at short intervals, and is aggravated by every conceivable accident, such as heat of the fire, or of the bedclothes, friction, stimulating food, mental emotion, and various other causes. It has been noticed—and my experience confirms the remark—that it sometimes occurs as an intermittent of a quotidian or semi-quotidian type. The mild form lasts generally but a few weeks, the more severe is rarely cured in less time than some months. The papulæ occur at first on the trunk, and spread thence to the extremities, omitting the face, scalp, and hands, which, by a compensating power as it were, are freed from this affection in consideration of their special liability to others. The disease is often complicated with forms of eczema, scabies, and ecthyma.

Prurigo senilis is described as having many varieties, but there are really not such, and the names are given because of its appearance on particular parts of the body, hence the terms Prurigo Scroti, P. Pudendi, P. Podicis, P. Præputialis, P. Pubis, P. Palmaris, P. Urethralis. The *Diagnosis* of prurigo from eczema, scabies, and other affections can, at times, be made only with difficulty; because, as already stated, it is frequently complicated with other skin diseases. In uncomplicated cases, however, the character of the eruption and the history of the case will suffice to make a diagnosis available for all practical purposes.

The *Prognosis* of the mild and severe forms of P. vulgaris is favourable; not so, however, with P. senilis, which often lasts through the life of the patient.

The *pathology* of the disease is a matter of controversy; Dr. Neligan considered it to be "chiefly a hyperæsthesia of the cutaneous structure;" and he believed that the changes in the state of skin attending it are usually produced by the local irritation occasioned thereby. M. Hardy believes the causes to be predisposing and occasional; and of them he observes:—"Nous nous sommes longuement étendu sur les dernières, le parasitisme et l'hypersthésie de la peau. Quant aux causes prédis-

posantes, elles reposent surtout sur les mauvaises conditions hygiéniques."—(Maladies de la Peau Partiè II., edit. 2., p. 91). The other opinions regarding the pathology of prurigo will be found on p. 240 of my edition of Neligan.

The *Treatment* in prurigo senilis has been sufficiently indicated in the example given above. In the other forms constitutional remedies should be chiefly relied on, but not to the exclusion of local applications. As the number of proposed plans of treatment is legion, the mere recitation of them would far exceed the limits of this paper. On this point see my edition of Neligan, pp. 240-244.

ON THE USE OF ARTIFICIAL SUPPORT IN CERTAIN FORMS OF DEAFNESS; WITH CASES.

By EDWARD BISHOP, M.D., M.B.C.S.E., &c.,
SURGEON TO THE EAR INFIRMARY, SACKVILLE-STREET, LONDON.

THE subject of appliances to the ear in cases of deafness attended by perforate membrana timpani is one of great interest. To Dr. Yearsley we are indebted for this addition to the therapeutics of aural practice; but the question of late has acquired additional interest from the enunciation of a fact which somewhat enlarges the sphere of their usefulness. Dr. Erhard of Berlin discovered that the wetted cotton remedy was of essential service to himself, although he had not a perforate membrana tympani, which had been set down by Yearsley as a sine qua non of its success. Erhard naturally directed his inquiries to the solution of the mystery; and during his investigations he discovered in the Museum of Pathology in Berlin a preparation, in which there was a disconnection of the incus with the stapes, with a loss of the os orbiculare; such solution of continuity appeared to him conclusive as to the modus operandi of the cotton wool in his own case, by the support it rendered in re-establishing the connection between the outer and inner membranes.

Those practitioners who have made aural disease a particular study, and have used artificial support in one form or another with success in cases attended with perforation, have, I doubt not, been led, like myself, to try its effects in obstinate cases where this lesion did not exist, and when successful have explained its operation as Erhard did. This explanation, however, and the consequent rational treatment founded thereon, has received additional confirmation lately. At a meeting of the Royal Medico-Chirurgical Society in February last, the late Mr. Toynbee exhibited a number of specimens of the apicula in situ, in which there was a disconnection between the incus and stapes; these specimens would have been more interesting and more valuable had he given their history, and been able to state to what extent functional derangement was coincident with structural lesion; but without this it was evident that such a condition is a less uncommon post-mortem appearance than has been suspected. In a paper read at the same time he adopted the explanation of the modus operandi of artificial applications in these cases, as given by Erhard, and also by Yearsley, in a paper read before the British Medical Association at Edinburgh—an explanation of course by no means novel. It speaks well for the candour of the late Mr. Toynbee, that he should have thus set forth his altered views on this disputed point. The practical objection to his artificial membrane of india-rubber or gutta percha is the distress and irritation it occasions; certainly it is difficult to abandon an ingenious invention, and therefore it is probable that Mr. Toynbee did not give in his adhesion to the simple and unirritating bit of cotton wool, but advised the use of a small hollow globe of india-rubber filled with air as a substitute for his artificial membrane—thus imitating as fa

as possible, without abandoning the material, the original remedy as proposed by Yearsley.

The following illustrative cases, I hope, will prove interesting:—

Case 1.—Miss M., of Canterbury, æt. 19, consulted me in August last. Her case presented the usual sad history of the ravages of scarlet fever. For several years she had been almost excluded from society, and her friends had quite abandoned the idea of treatment, as she had some years before tried the use of Toynbee's artificial membrane, which caused such distress she could not use it. The left ear was completely disorganised, a considerable part of the temporal bone was gone, and of course nothing could be done. The right ear showed a perforation of the membrane, and there was a little discharge issuing from the meatus; she could not hear a watch when in contact, and the tick of a loud metronome was very indistinct. I inserted the wetted cotton support in the usual way, and immediately she could hear my voice, and enter comfortably into conversation. I dare not attempt to occupy your space by giving the details of this interesting case, but in less than a fortnight's time she could apply the cotton herself very well, and was able to join in general conversation with ease, and expressed all the delight of a person having so important a sense suddenly restored.

Case 2.—S. W., a tailor, admitted (Ear Infirmary, Sackville-street) July 6th, 1866. Very emaciated; deaf for last ten years; for two or three years non-progressive, until recently, when he found himself much worse, and now is suffering from pain and singing in each ear, and is almost perfectly deaf, the eyes injected, skin hot, pulse 110. Ordered an aperient of calomel and colocynth, saline mixture, and three leeches to each ear.

9th. Relieved of all acute symptoms, tinnitus subsided.

13th. Is now as well as he has been for many years. Hearing distance (by watch) one inch right ear, contact only left ear, both membrana tympani white and pearly, no perforation, ear wax absent, Eustachian passages open, throat slightly sore, tonsils somewhat enlarged. Applied solution of nitrate of silver to throat, and used artificial support (wetted cotton wool) on each side. The hearing was at once improved; he could hear the tick of the watch twelve inches away on the left, the worst side, on the right only about half this distance; conversation he heard comfortably without much effort. In three weeks' time the patient could adjust the support himself, and can now hear the tick of the watch more than twenty-four inches from each ear. Can we account for the marked improvement in this case in any other way than that there was a disconnection of the chain of bones as they traversed the cavity of the tympanum?

OBSERVATIONS UPON THE PATHOLOGY OF ANTHRAX AND BOIL.

BY B. WILLS RICHARDSON, F.R.C.S.I.,

SURGEON TO THE ADELAIDE HOSPITAL, DUBLIN.

THE discrepancy of opinion still existing as to the exact nature of the core of boil and anthrax induced me to investigate this question, especially with a view to determine if there be grounds for the supposition that the cores are composed merely of effused lymph, the result of the inflammatory process. One would think that such an investigation was uncalled for, when so many excellent authorities have so ably combated this view, and proved that the old ideas on the matter contain more of truth than the false membrane theory of Gendrin, Denonvilliers, Nélaton, and their followers.

The writings of some of the older authors prove, even as regards anthrax, they were most accurate observers of the structural alterations caused by disease; which is the more remarkable when it is remembered they were unprovided

with the excellent appliances of the modern pathologist for minute investigations, and shows that accurate deductions may be made from observation with the unassisted, but educated eye. And it moreover proves that teachers should endeavour to impress upon the student that, previous to having recourse to magnifiers, he should first familiarize the eye with the appearances of the morbid structural alterations of tissues.

At the risk of being considered tedious, I venture to remind the reader of a few of the opinions of the writers just referred to, regarding the nature of the core of anthrax and boil.

Dupuytren's name being so identified with the strangulation view, and his opinions are so explicit upon the subject, that it will be necessary to mention them here in detail.

Dupuytren considered that anthrax is nothing else than inflammation of several packets of cellular tissue contained in the areolæ of the derma. He describes the "derma as thick, white, and elastic, more consistent at its external than internal surface; composed of fibres, which, by their interlacing, form areolæ. Irregularly placed beside each other. Each of them is filled by a packet of cellular tissue, which, sometimes being impregnated with a large quantity of fatty fluid, distends the cells which contain it. The numerous areolæ of the derma have all a nearly conical form. Their summit corresponds to the reticular body, and their base to the internal surface of the skin, which reposes in all parts upon a layer of cellular tissue."

He next gives the following account of the changes which occur in the skin, in the site of the anthrax. "Anthrax only differs from furuncle, by the extent and multiplicity of the cellular packets which are inflamed at the same time." He alludes to the fact, that anthrax had been often confounded with the *charbon* and the malignant pustule. "Varieties of a disease essentially gangrenous; in the anthrax, on the contrary, the gangrene is the consequence of the strangulation, the incision is its true curative means."

M. Sanson described "anthrax as an inflammation of the processes of cellular tissue which accompany the vessels and nerves through the true skin. That it differs only from furuncle in the extent of cellular tissue engaged. In both cases the malady terminates by the formation and fall of an eschar, or *bourbillon*, formed in the one part, at the expense of the inflamed areolar tissue, and on the other part, at the expense of the fibrous partitions which separate the areolæ of the derma, the mortification of the first, is the result of the resistance which the fibrous tissue of the chorion opposes, on account of its great power of swelling, and consequently from the compression and strangulation which it experiences. The mortification of the walls of the areolæ of the derma depends; on the contrary, on the distension to which they are submitted by the cellular tissue attempting to swell; there is gangrene by *compression* of the contained parts, and gangrene by *distension* of the containing parts."

"As regards treatment, he is to be numbered with those surgeons who advocate incisions, for he considered that the most certain treatment consists in unbridling the tumor by the aid of incisions, which divide it from its summit to its base. "They facilitate the escape of the pus already formed, and the fall of the areolar flocculi already stricken with death."

Sanson was also an advocate for the use of compression after the incisions were made; for, he recommends that the consecutive treatment should consist "in making, during the first days which follow the operation, *methodical pressure*, which expels the pus and detached cores."

M. Margolin held almost identical views. "Anthrax," he observes, "has its seat in the adipose tissue contained in the areolæ of the derma, and in the subjacent areolar tissue. This tumor constantly terminates by mortification of the areolar tissue which forms it, and by destruction of a portion of the skin which covers it." This writer also considered the disease a depurative one, a belief held by many other observers.

Speaking of the treatment, he likewise makes a remark

of some interest, when we recollect the suggestions of recent writers regarding it. "I have seen," says he, "a patient arrest the progress of a benign anthrax, and cause the insupportable pain which he experienced, to cease promptly, by applying to the tumour, compresses, moistened with very cold water." But he thought that this repercussive treatment might be dangerous, if the malady proceeded from an internal cause. Notwithstanding the effect of the compression in the case of the patient he alludes to, he impresses upon the reader the importance of remembering "that anthrax is an essentially inflammatory tumour; that it terminates by gangrene only because the areolar tissue experiences a true strangulation. He therefore approved of the circular incision of Lallement for certain cases, and Dupuytren's crucial incision for others."

Having given the views held by some of the most eminent surgeons of their time, it now remains for me to state the opinions of M. Nélaton, who, so far back as 1844, raised doubts regarding the accuracy of these views.

M. Nélaton's description of the core of anthrax is the more extraordinary, considering that the nature of the core could, we think, be easily decided by a simple microscopic investigation of it.

Speaking of the nature of the core of anthrax, he asks, "What is the nature of the core? Is it to be considered an eschar of cellular tissue, or a simple product of secretion? The inflammation having been localized in the cellular bundles of the areolæ of the derma, authors delight to describe in these areolæ contained and containing parts; the first susceptible, when they are irritated, of acquiring a greater volume; the second, dense and resisting; whence they have been led to think that there was strangulation and gangrene of the areolar tissue, and that this tissue, isolated later by the suppuration like all eschars constitutes the core." "We say at once that this theory contains a double error—that there is no strangulation; that the core is not gangrenous areolar tissue, but a simple product of secretion, a veritable pseudo-membrane. (1.) *There is no strangulation.*—Indeed, the areolæ of the derma, the conical ones, others hemispherical, are all so disposed, that they correspond by a base widely expanded to the subcutaneous areolar tissue. Consequently, when the inflammation attacks the adipose cellular tissue lodged in these areolæ, this tissue slightly pressing back the subjacent areolar layer will be able to develop freely, and arrive at the greatest augmentation of volume, without encountering any obstacle from it. Perhaps it will be objected that the intra-dermic adipose packets are fixed in the interior of the areolæ by the vessels and nerves which traverse them to finally expand in the papillæ; that thus expanded by an inextensible pedicle, they cannot abandon the too narrow inclosure which they occupy, and that they present from that moment conditions most favourable for strangulation and gangrene. But we may remark that the widest part of these bodies corresponds to the subcutaneous adipose layer, that in all cases this part can develop itself freely. Consequently, in admitting that the vessels and nerves retain in the areolæ the cellular tissue lodged in them, strangulation will only be possible for the parts of this tissue which correspond to the summit of the areolæ; these parts alone will be stricken by death, and the eschar will be infinitely small. Now, the core exceeds in volume that of a hundred adipose cellular packets united in a single mass; it is, therefore, much more considerable than it ought to be if it was the result of mortification of the intra-areolar cellular tissue. We may add that gangrenous parts, at the period of their elimination, have a characteristic tainted odour, and that the core is without smell; that in an eschar we find most of the elements of the organ which has been deprived of life, the vessels principally; and that in the core we do not observe any trace of organization." "That the cellular tissue, which becomes gangrenous, in consequence of violent inflammation, dies at the moment only when this inflammation acquires its highest degree of intensity; and that the core exists long before this period, for we find it quite formed in the tumour

from the moment of its appearance, and then, as at a later period, it does not present any appearance of vessels. We may, therefore, conclude that the form of the areolæ excludes all idea of strangulation; likewise that the volume of the core, the absence of characteristic odour, its inorganic state, its existence at the commencement of the inflammation, exclude all idea of gangrene. (2.) *The core is a product of pseudo-membranous secretion.*—When serous membranes inflame, they sometimes become covered with false membranes; the cellular tissue, which presents in structure a great analogy to the serous system, its functions, and its diseases, secretes also, under certain circumstances, a white matter, slightly yellow, albumino-gelatinous, which is deposited in the meshes, where it concretes. This pseudo-membranous product is primitively very adherent to the dense and red cellular tissue which surrounds it; but a fluid at first albuminous, then a veritable pus is effused around it; it becomes less adherent, detaches, isolates itself completely, and floats as a foreign body in the small purulent collection which has formed, until this has found an exit, and carried it outwards. After this elimination, the inflammation diminishes rapidly, as well as the volume of the tumour; cicatrisation is accomplished in two or three days; the cicatrix is circular, of small dimension, and scarcely apparent."

M. Nélaton held views similar to those of Gendrin regarding the cores of furuncles. Thus he states that "the presence in a furuncular eruption, of a pseudo-membranous body, secreted in the commencement of the inflammation, and at a later period constituting a foreign body, gives to this affection a special character; indeed, there results that the furuncle ought most often so to terminate in suppuration, and that cicatrisation can commence only when the expulsion of the foreign body shall have taken place."

As regards the theory of the strangulation of areolar tissue in furuncle, he says:—"Authors being unanimous in believing in strangulation of the cellular tissue in this affection, have been equally so upon the necessity of practising incision. In the immense majority of cases, he, on the other hand, believes that "the incision prolongs the accidents, far from hastening their resolution. His views on the treatment of anthrax, particularly as regards incisions, are precisely similar. "The anatomical characters of anthrax are in every respect similar to those of furuncle; the volume alone of the tumour establishes between these two affections a difference which is far from justifying the isolated description which all authors have given of it, which does not even justify completely the distinction of the two varieties that we have admitted, but that we maintain, however, in order that we do not depart too much from the usage generally adopted.

"When the inflammation is propagated to a great number of intra-areolar, adipose-cellular packets, the resulting tumefaction is considerable; but, as it bears upon a greater surface, and as each of the parts comprised in this surface tumefies equally, the tumour loses the conical form proper to the furuncle to assume that of a segment of a sphere, through the openings, which subsequently form again." Alluding to the false-membrane, he says that, "we can express the pus and the pseudo-membranous product which constitute the core."

M. Nélaton, being guided, I suppose, by his ideas as to the pathology of furuncle and anthrax, proscribes incisions. At each dressing he recommended moderate pressure to be exercised over the base of the tumour, in order to facilitate evacuation of the pus and all the pulpy matter composing the core. "Emollient applications, complete repose, a bland regimen, and mild purgatives, if the anthrax is connected with a general state, will complete the cure."

Why M. Nélaton concluded, that the cores of furuncle and anthrax are merely composed of pus and lymph, he does not say, neither does he mention, if any minute examinations were made of the cores in question. It may be assumed, however, that such examination was not made, for, it requires but little microscopic experience indeed, to ascertain that these cores are, to a large extent, composed of

yellow and white elastic tissue, in addition to pus and lymph.

As I have mentioned before, Gendrin's views as to the structure of the core of boil, were similar to the subsequent views of Nélaton and Denonvilliers regarding it and the core of anthrax. Gendrin, as positively as Nélaton, denied that the cores are sloughs, asserted that they are morbid secretions or pseudo-membranes, the product of the inflammation of the inter-areolar cellular processes, and that they consist of a viscid, semi-transparent, homogeneous, yellowish-white substance, without any vessels, and without the least trace of organization.

Gendrin, like Nélaton, could scarcely have made such a mistake unless he also omitted to make a minute examination of the cores. If he had only done so, with very little trouble he would have found plenty of areolar tissue in them.

The adoption of the views of Gendrin, Denonvilliers, and Nélaton, by subsequent writers, illustrates very forcibly how liable we are to take for granted as correct, opinions which are promulgated with earnestness, and particularly if done so by men of character and repute. As regards the cores of anthrax and boil, there is no excuse at the present day for such credulity, more particularly as their pathology has been accurately described by some of our cotemporaries. Indeed, so far back as 1835, Carl Wedl published, in his work on the Rudiments of Pathological Histology, an illustration of yellow elastic and white fibrous tissues from the core of an anthrax. Wedl's illustration, however, was most probably overlooked, his work having been translated into our language only within the last few years.

The observations above quoted from M. Nélaton's book appeared in 1844; but, although he then condemned incisions in anthrax, he has recently modified his opinion, having written to Dr. O'Ferrall the pioneer of the recent re-introduction of the compression treatment, that he now recognises the utility of incision. But Monsieur A. Guérin, as well as I can remember, does not say whether M. Nélaton was led to do so by a change of opinion regarding the nature of the core, or from practical advantages following the use of the knife.

Fig. 1.*

Having had many opportunities of recently examining the cores of boils and of anthrax, I have not failed in any case to find yellow elastic and white fibrous tissue; so that the description of the core, as given by Sir Benjamin Brodie, I believe to be strictly accurate—namely, that it mostly consists of cellular membrane infiltrated with pus and lymph.

Last year a man was admitted into the Adelaide Hospital, who suffered from a succession of boils, the cores of which, in addition to pus and lymph, contained a large quantity of areolar tissue. (Figs. 1 and 2.)

* White fibrous tissue from core of boil—230 diameters.

Fig. 2.*

* Yellow elastic tissue from core of boil—230 diameters.

Represents some of this tissue drawn with the aid of the camera.

Just about the same period a woman was admitted under the care of Dr. Walsh, with an anthrax, which commenced on the chin, thence engaging the lip, floor of mouth, and front of neck. This woman subsequently died, with symptoms of blood-poisoning and rapid destruction of the left eye. The anthrax sloughs in this case I repeatedly examined, and found that they likewise were largely composed of the tissues represented in Figs. 3 and 4.

Fig. 3.+

+ White fibrous tissue from core of anthrax—230 diameters.

I have examined many furunculi and anthrax sloughs since then; but as they were identical in structure to those illustrated, it was unnecessary to take drawings of them.

I must refer the reader to systematic works on surgery for the various opinions regarding the other points about anthrax, my sole endeavour in this paper being to show that there are very slight grounds, indeed, for the supposition that the cores of either boils or anthrax are solely of a false membrane nature: yellow elastic, and white fibrous tissue entering largely into their composition. If I may venture, however, to speculate regarding the local treatment deducible from the knowledge we possess of the local changes that take place in anthrax, I would say, incision, in a large majority of cases, ought to be the proper procedure; or rather, incision followed by judicious strap-

Fig. 4.*

* Yellow elastic tissue from core of anthrax—230 diameters.

ping, as advised, amongst others, by Sanson. There can be no doubt, however, that there are forms of anthrax which will get well without incision. Some, for instance, as M. Guerin reminds us, only lasting from ten to fifteen days. Cases of this kind forewarn us how difficult it is to draw any safe conclusion regarding the efficacy of local treatment, as we cannot tell beforehand what would be the natural history of such a case. Apply this observation to either compression or incision of anthrax. Suppose, for instance, we had to treat a case which naturally would have had a short duration, whether we incised or compressed it, how liable would we be to fall into the error of attributing to our interference the rapid subsidence of the malady?

I have myself seen anthrax so often cease to extend after incision was practised that I am prejudiced in its favour, at least in acute cases. On the other hand, I have recently seen compression tried in two individuals, according to the principles directed by its advocates, but the anthrax of each was found to have broken fresh ground at every morning visit, having since the previous dressing extended beyond the plasters. In both cases incisions were subsequently made, and no further extension of the anthrax took place.

Correspondence.

MEDICAL CLUB.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reply to your numerous correspondents I beg to direct their attention to the arrangements now in progress for the temporary accommodation of the members of the above Club (see advertisement), which arrangements I hope the Committee will shortly be able to render more complete by the enrolment of additional members, and an increase in the amount of their contributions.—I am, sir, your obedient servant,
LORY MARSH, Hon. Sec.

EPISTAXIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Reading Dr. Ballard's paper on "Epistaxis," in a recent number of your journal, I thought the following statement of a plan I have found very efficacious, might not be unacceptable.

In this town there are, I imagine, more schools—"good, bad, and indifferent"—than in any other place in the kingdom—perhaps in the world, if, as I am assured, there are upwards of three, and nearly four hundred; and living as I do, surrounded by quite a population of school-boys and

girls, you will believe that epistaxis is by no means uncommon; indeed, so often am I summoned to such cases that for a long time past I have kept in readiness for immediate use the following styptics, in equal parts, well rubbed together in very fine powder—viz., matico, sulphate of zinc, and alum.

In several cases the merely taking a good pinch of this, in the same way as snuff, has stopped the bleeding; but where it has failed I have at once plugged the nostril with small pellets or pledgets of dried sponge charged with the powder, then firmly compressed and inserted by means of any blunt instrument, and nothing can be better than the thin or thinned end of a pen-holder.

The sponge expands as it becomes charged with blood, and thus plugs the nostril more effectually. I believe the powdered matico alone would suffice, and mean one of these days to try it.—Yours very obediently,

JAMES BARKER, M.D.

Brighton, December, 1866.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I suffer, and have suffered for some months back, from a horrible complication of "sounds, sensations, and functional deficiency" in my left ear. The symptoms from which I experience most annoyance are, the incessant "ringing, cooing, whistling, and hushing"—accompanied by a feeling of insensibility and serious deafness. Never having devoted much attention to the affection of the auditory apparatus, I should feel sincerely grateful to any one of your correspondents who would, through the medium of your excellent periodical, afford me an outline of the treatment to which my malady should be subjected.—Meanwhile believe me, dear sir, yours very truly,
MISER.

TESTIMONIAL TO MR. BAKER BROWN.—Our readers will observe from the list of subscribers which we publish in our advertising columns to-day that the Brown Testimonial is receiving a cordial reception from the profession. The list of subscribers is wanting neither in professional rank or numbers to entitle it to full consideration and respect.

We regret to learn by the last Indian mail that while some of the officers of the 2nd Battalion 25th (King's Own Borderers), were practising pistol shooting at Colombo, Ceylon, an accident occurred which resulted in the death of Ensign H. W. Thompson, by a shot fired by Dr. Evatt, assistant-surgeon of the battalion. A coroner's inquest was subsequently held, at which Dr. Evatt was exonerated from all blame.—*United Service Gazette.*

DR. BENJ. JOHNSON, having resigned as Medical Officer of the Carrigaline Dispensary District, in the Cork Union, from ill-health, after thirty-eight years' service, has been presented with a salver and a purse containing one hundred sovereigns, accompanied by an address couched in very warm and earnest language, signed by the chairman and hon. secretary of the Dispensary Committee, acting for the residents of the district.

THE NEW FRENCH PHARMACOPŒIA.—This book is undergoing the same ordeal as befel our British Pharmacopœia. M. Jeannel, of Bordeaux, takes the editors to task in *L'Union Medicale* of the 1st instant, and shows a pretty large number of shortcomings. The editor of the journal publishes the criticisms with some apprehension, as medical papers are not allowed to touch on subjects of political economy.

THE CASE OF MR. STATHAM---A public meeting of the medical and dental professions was held on Tuesday at the Literary and Scientific Institute, Edwards-street, Portman-square, to receive the report of a sub-committee appointed at a preliminary meeting on the 20th of last month, and to unite in an expression of sympathy and confidence in Mr. Statham. The case of Mr. Statham had its origin in the administration of chloroform by that gentleman to a patient of the name of Absolon at the Great Northern Hospital during an operation for the extraction of teeth. An action was afterwards brought by the patient against Mr. Statham, who was thus exposed most unjustly, as his professional brethren believed, to considerable expense and trouble. Sir William Fergusson, Bart., presided at the meeting, and about fifty or sixty other members of the medical and dental professions were also present on the occasion. The sub-committee reported that as Mr. Statham had expressed his unwillingness to receive any sum for the purpose of enabling him to defray the cost he had incurred in his defence before a court of law, it was not advisable to take any step for that object, and after several gentlemen, including some of the colleagues of Mr. Statham at the Great Northern Hospital, had expressed their conviction of his perfect innocence of the maltreatment of his patient with which he had been charged, and their knowledge of his great kindness and attention to the poorer class of persons who were brought under his care, a resolution was unanimously passed by the meeting declaring that in their belief the professional treatment which he had adopted in the case of the plaintiff, Absolon, was in every particular sound, skilful, humane, and beyond reproach; that they warmly sympathised with him in the expense and anxiety he had incurred in conducting his defence; and that they had the fullest confidence in his professional skill, integrity, and honour. It was added that, but for Mr. Statham's own objection to such a course, the meeting would gladly have defrayed the legal expenses to which he had been subjected. It was further resolved that a copy of this resolution be engrossed on vellum and presented to Mr. Statham. A vote of thanks to the eminent chairman was then proposed and seconded; and Dr. Richardson having alluded in high terms to the zeal and energy displayed by Mr. Fox, the hon. secretary, the proceedings terminated.

MR. CÆSAR HAWKINS, F.R.S.---At a meeting of the Council of the Royal College of Surgeons, on the 13th inst., a letter from Mr. Cæsar Hawkins was read, in which he expressed a desire to resign his seat as a member of the Court of Examiners. In accepting the resignation the Council expressed deep regret at the retirement after so many years of so esteemed a colleague. It may be interesting to our readers to know that so long ago as 1846 Mr. Hawkins was elected a Councillor, and was fortunate enough three years afterwards to become a member of the Court of Examiners and the Hunterian Orator. In 1852 he was elected President of the College, and again filled the chair in 1861. At a recent election of Councillors, the Fellows, feeling that Mr. Hawkins had held office long enough, displaced him in favour of a more popular candidate. It is hoped and generally expected that the good example thus set will be followed by more than one other member of the Court. Mr. Hawkins retains his seat at the General Medical Council as the representative of the College of Surgeons.—*Lancet*.

HEALTH OF SCOTLAND---The Scottish Registrar-General has to report that the deaths in the eight principal towns in November were 2427, a number below that of November in last year, but 140 above the average in the past ten years, allowing for increase of population. In these towns, with an aggregate population approaching a third of that of the metropolitan district of England, there were in November, 203 deaths from cholera, and 63 from diarrhœa. In Glasgow there were 6 deaths from cholera and 22 from diarrhœa; in Edinburgh, 86 from cholera and 13 from diarrhœa; in Leith, 23 from cholera and 3 from diarrhœa; in Dundee, 48 from cholera and 8 from diarrhœa; in Aberdeen, 26 from cholera and 9 from diarrhœa; in Paisley, none from cholera, three from diarrhœa; in Greenock, four from cholera and three from diarrhœa; in Perth, 10 from cholera and 2 from diarrhœa. The deaths from cholera constituted 13·5 per cent. of the mortality in Aberdeen, 14·9 per cent. of the deaths in Dundee, 17·6 per cent. of the deaths in Edinburgh, 19·2 per cent. of the deaths in Perth, and 26·1 per cent. of the deaths in Leith. Typhus caused 142 deaths, or 5·8 per

cent. of the mortality. This disease proved most fatal in Paisley and Leith, causing 11·4 per cent. of the deaths in the former, and 10·2 per cent. of deaths in the latter town. In October the deaths from cholera were 167—95 from diarrhœa, 122 from typhus. The marriages in November, 930 in number, were considerably above the average. The births, 3010, are the highest registered in November since civil registration was established, in 1855. The meteorological characteristics of the month have been a constantly low barometrical pressure, and a remarkably constant direction of west wind; large also in amount; the mean temperature at the same time being rather high. The thermometer was several times below the freezing point, but not to so great a depth as the average of former years. The mean temperature was 42·3—above the average by 1·5. The highest recorded mean temperature was at Leith, 44·1; and the lowest at Aberdeen, 39·6. The greatest depth of rain-fall was recorded at Greenock—5·62 inches; and the least depth at Dundee—1·60 inch.

SAMANDARINE---The poison of *Salamandra maculata* is obtained in the form of a milky liquid by grating the posterior parts of the head and back of the animal on the edge of a spoon or the back of a scalpel. The liquid which exudes is white, viscous, strongly alkaline, and bitter; and contains a quantity of globules which disappear when alcohol, ether, and acetic ether, are added. The symptoms provoked by the absorption of samandarine, or of the secretion itself, succeed each other in about half an hour in the following order:—anxiety, trembling, epileptic convulsions, opisthotonos, and death. Dr. Zalesky's method of isolating the poisonous body is given in the *Bulletin of the Chemical Society of Paris*, 1866, p. 344. Its composition is, carbon, 34; hydrogen, 60; nitrogen, 2; oxygen, 5.

On the 28th ultimo an order was made by his Excellency the Lord Lieutenant and Privy Council, appointing Wm. Scott, Esq., M.D., J.P., of Castletown Bawn and Aughnacloy, a Governor of the District Lunatic Asylum at Omagh, for the counties of Tyrone and Fermanagh.

COMPARING 1866 with 1865, there is a decrease in pauperism of 9329, or 4·5 per cent.

Notices to Correspondents.

Communications to the Editor should be addressed to 20, King William-street, Strand.

Every MS. should bear the Name and Address of the Sender.

All Contributions are attentively considered, and unaccepted MSS. are returned on receipt of stamps for postage; but the Editors cannot be responsible for any accidental loss, nor can MSS. or replies be delivered on personal application.

Contributions should be legibly written, and only on one side of the paper.

When proofs are forwarded it is of the utmost importance that they should be corrected and returned without delay.

ON EMBOLIC PHTHISIS AND TUBERCLE,

BEING THE SUBSTANCE OF SOME CLINICAL OBSERVATIONS

MADE BY

ANDREW CLARK, M.D., F.R.C.P.,

PHYSICIAN TO THE LONDON HOSPITAL.

(Continued from page 618.)

Case 3.—(Reported by Mr. R. C. Sanders.)—Mary Floright, æt. 25, a widow, was admitted into the London Hospital as an extra case, under the care of Dr. Andrew Clark, on the 19th September. On admission patient appeared in a state of extreme agony. The face was puffed, and of a deep bluish-white colour; the base of the throat was swollen and the jugulars enormously distended, and occasionally pulsatile. Unable to lie down, patient sat up in a state of constant unrest. The respiration was laboured, and at the rate of forty per minute. When questioned, patient replied in broken whispers of a word or two at a time. The heart was acting violently and irregularly in points of force and time; and its impulse was visible over nearly the whole cardiac region. The pulse weak, thready, quick, and irregular, could not be counted. The cardiac dulness was increased to the right side above and below; no murmur was discernible, and the exact character of the heart's sounds could not be determined by reason of their rapidity. Patient had an incessant short dry cough, and suffered, as far as one could make out, from constriction of the chest and a sort of agony about the heart.

It appeared, from inquiries subsequently made, that the patient had had rheumatic fever two years ago, and that though, as she believed, the heart was not at that time affected, she has ever since been liable to attacks of palpitation on occasions of extra emotion or exertion. It further appeared that for some days before admission she had been troubled with continual palpitation, which, on the day of her entry into the hospital, became suddenly and inexplicably worse, and accompanied by distress of breathing.

The patient was first seen by the Resident Medical Officer, who ordered a drachm of tincture of digitalis every four hours, and a blister to the heart. These means relieved the patient during the night, but next day she again became worse and was seen by Dr. Andrew Clark. At this time the patient was described as in much the same condition as when admitted, saving that the pulse and respiration had fallen in frequency, that the skin was bathed in sweat, and that there was less distress. A more general examination was now made. The tongue was bluish and dry. There was frequent retching. The bowels had been for some days confined. Patient was subject to profuse menorrhagias. The urine, though not scanty, was high coloured, very acid, and deposited an abundant sediment of purple coloured lithates. The heart was in the condition above described. There were dull spots over various parts of both sides, and, except at the bases of both lungs, where there was an occasional coarse crepitus, the respiratory murmur was everywhere feeble. Patient could now speak a word or two audibly, and complained of a dreadful feeling in her heart and chest, over which she frequently passed her hand. The

condition and relations of the clot. Meanwhile he suspended the digitalis, ordered the bowels to be well cleared out, mustard sinapisms to be freely applied to the extremities, and a draught containing bi-carbonate of potash, ammonia, and ether to be taken every two hours. He further directed that unless the dyspnoea cardiac distress and jugular distension were sensibly relieved towards evening the patient should be bled. The patient was recommended to take warm fluids freely, especially the chlorate of potash, lemonade. In the evening she was sensibly relieved, and during the night had, with the help of henbane, a couple of hours sleep. In the early morning of the 21st the patient complained of occasional sensations of stoppage of the heart's action, accompanied by sudden fright and feeling of approaching death. Seen at one of these times by Mr. Sanders, he described the heart as acting tumultuously, with sudden intermissions, and the breathing as dreadfully laborious and distressing to witness. In the afternoon patient looked and felt much better. The bowels had been freely opened several times, and urine had passed in great abundance. The face was clearer and less anxious, the neck less swollen, the manner more composed. The cardiac dulness was still increased, and the heart's action, irregular in force and rhythm, but it was stronger, and its sounds could be discriminated. Two murmurs were now audible—one, heard in a circumscribed space over the cartilages of the left third and fourth ribs, was low-pitched, intermitting, and heard just before or at the beginning of the ventricular contraction; the other continuous, blowing, best heard at mid-sternum, from whence it could be followed for an inch and a half upwards to the left side, where it suddenly ceased, was synchronous with the contraction of the ventricles. The first murmur was only audible within a space which might be covered by a crown piece. No murmur was heard in the course of the aorta. The pulse was about 120, small and irregular. There was rather more cough and some frothy mucus expectoration streaked with blood.

Medicines were ordered to be continued every three hours, and linseed poultices to the chest.

On the 23rd patient was, in some respects, very much better; the face though pale was not livid; the swelling of the throat had almost subsided, and there was no jugular reflux. The first-described murmur had disappeared; the basic systolic bruit was louder than before, but audible in exactly the same situation; the heart's action was stronger and not continuously irregular; the pulse was 110; the general temperature better; the skin moist but not clammy. On the other hand, there was more cough, more mucoid expectoration streaked with blood, and greater pain about the chest and shoulders. In certain spots already noticed dulness was more marked; the respiration therefrom being feeble had become blowing; and there were sundry places in the upper part of both lungs where a coarse crepitus was heard with both the inspiratory and expiratory sounds. Dr. Clark inferred that secondary deposits had occurred in the lungs.

A blister was applied to the chest, the bowels were directed to be kept lax by a gentle saline, and bark was made the basis of the alkaline mixture, which was now given only four times a day.

On the 26th the patient was so much improved that, but for her cough, she would have considered herself well. The tongue was clean; the appetite returning; bowels lax; urine normal—it had never become alkaline. The heart beat about 96 times a minute and had become quite regular. A loud blowing systolic bruit was however still heard about mid-sternum. Less distinct below, and to the side above, it was audible only within narrow limits

streaked with blood. The respirations were about 24 per minute. The temperature rose towards evening to 101° in axilla.

The mixture was now omitted. Patient was allowed four ounces of wine a day. Morphia, laurel-water, and glycerine were prescribed for the cough as occasion might require; and she was directed to take thrice daily a mixture, containing ammonio-citrate of iron, iodide of potassium, ammonia, and infusion of calumba.

On 4th October patient was in every way better, she had gained fresh strength and some colour. Her only complaint was of a little cough and shortness of breath. The heart's action was quite regular, although the systolic bruit remained; the pulse was about 80; cough and expectoration had diminished; the breathing, however, was still hurried, and the dull spots with blowing and now divided respiration were just as before.

Patient having shortly afterwards expressed herself quite well, was discharged at her own request, but is still under occasional observation.

Dr. Clark observed that the events in this case appear to have begun with the formation of a small clot in the right auricle; that on the morning of the 21st portions of it got broken off, and carried through the right ventricle to the lungs, where they became impacted in branches of the pulmonary artery, too small to permit their passage; that there they excited secondary changes, issuing in solidification either in parts immediately adjacent or in parts at a distance by crumbling into minute particles, which reached and blocked the capillary circulation. He thought it probable that the murmur first heard was produced in the auricle, and that the second, which still remained, took its origin in the pulmonary artery; but he did not stay to discuss the mechanism of their production. It was not clear what led to the intra-cardiac clotting; but there were in the case many conditions to favour it: a past history of rheumatism; acid secretions; fits of palpitation, and a sedentary life. The future of this case, both as regards the heart and lungs, is full of interest. It is more than probable that the heart attack will return, or that the valves will be slowly altered by organic disease. In the hope of averting such a result Dr. Clark recommended the woman to be careful of her doings and diet; to eat plenty of green vegetables; to drink no beer, and to take small doses of potash whenever the urine became thick. But the woman went out, not only with a damaged heart, but with sundry deposits in her lungs. What is to become of these deposits? Will they be absorbed, converted into calcareous concretions, or broken down into small abscesses? It is hard to say. Only one knows that where the heart is diseased the softening of such deposits is exceptionally rare.

Dr. Clark concluded by saying that such cases were not rare; that the pulmonary embolic deposits when not absorbed became like yellow tubercles; and that by the softening of these, and the secondary changes which that softening involved, there was induced a spurious phthisis, not easily distinguishable during life from the true phthisis, which has the grey granulation for its anatomical characteristic.

CASES OF SOFTENING OF THE BRAIN.

By JOHN W. OGLE, M.D.,

PHYSICIAN TO, AND LECTURER ON MEDICAL PATHOLOGY AT, ST. GEORGE'S HOSPITAL, ETC.

(Continued from page 569.)

SOFTENING (GENERAL) OF THE BRAIN; DISEASED KIDNEYS AND HEART; CONVULSIONS.

Case 94.—John M., aged 53, was admitted June 20, 1853, with pains in the limbs, increased heart's action, dyspnoea, and shivering. Also a double aortic-valvular bruit, and pericardial-friction sound existed. It was stated that he had been ill but five weeks. In spite of treatment, drowsiness

came on, and pain at the back of the head; and, eventually, convulsions and delirium. He died in an attack of convulsions July 2nd.

Post-mortem Examination.—Thorax and Abdomen.—The heart was hypertrophied, and the effects of pericarditis existed. The kidneys were highly granular and cysted. *Cranium.*—The arachnoid membrane was opaque, in many parts much fluid existed beneath it, and in the ventricles. The brain, throughout its substance, was decidedly softer than natural. (189.)

SOFTENING OF THE CENTRAL WHITE PARTS OF THE BRAIN; FEVER.

Case 95.—James S., aged 34, was admitted January 20, 1854, with fever and delirium. He sank and died January 30th.

Post-mortem Examination.—In addition to congestion and an emphysematous state of the lungs, and a slight ulceration of the ileum, very extensive softening of the central white parts of the brain was found, along with much fluid in the ventricles, and beneath the arachnoid membrane. The brain itself was pale. (41.)

SOFTENING OF THE CENTRAL WHITE PARTS OF THE BRAIN; COMA BEFORE DEATH.

Case 96.—Charlotte A., aged 20, a stout and well-fed girl, was admitted March 8, 1854, having been for a week suffering from pain in the head, and having also been sick. There had been no pain elsewhere, but she had for years been subject to discharge from the ears. The pulse was quick and weak; the tongue foul. The eyes were suffused and with a slight tendency to strabismus, but the pupils acted naturally. She was deaf, and spoke slowly in reply to questions, and was rather confused in thought. In spite of treatment she passed into a state of insensibility; lividity of the surface came on, and, without any convulsive movements, she died four days after admission.

Post-mortem Examination.—Cranium.—Bones of the skull natural. The veins of the membranes were full of blood, and the cerebral convolutions flattened. Much fluid existed beneath the arachnoid, at the base of the brain, and much turbid fluid in the lateral ventricles. The fornix and septum-lucidum, and superficial parts of the corpora striata were very softened, otherwise the brain was natural. Excepting slight adhesion of the capsules to the kidneys, which were striated, the other organs of the body were natural. (66.)

SOFTENING OF THE SEPTUM-LUCIDUM; CONGESTION OF THE MENINGEAL VESSELS; COMA, HEADACHE, AND CONVULSIONS BEFORE DEATH.

Case 97.—Edward A., aged 32, a groom, was admitted March 29, 1854, having been found in a room, lying partially insensible, as if recovering from a fit, and could give no account of himself. He had an uncertain look with his eyes, and at times double convergent squint, but generally divergent squint. The pupils of the eyes were natural. He was cupped on the loins, had a blister to the nape of the neck, and a turpentine injection. On the day following he was more conscious, and had much pain in the head; and in the evening there was a return of the convulsions, and he had seven epileptic attacks, which left him unconscious. He remained in a stupid state, with his eyes generally turned outwards. He never rallied, and died April 2nd.

Post-mortem Examination.—Thorax and Abdomen.—The lungs contained scrofulous deposit and vomica, and the heart was very softened. *Cranium.*—The meningeal vessels were very congested. Much fluid existed under the arachnoid membrane, which was rather opaque and thickened. The brain was very dark and the ventricles distended, and the septum-lucidum was very softened. (93.)

SOFTENING OF THE SEPTUM-LUCIDUM; PHTHISIS.

Case 98.—Samuel B., aged 24, was admitted March 25th, 1854, having been out of work and starving, and laid

up for a week. He was unconscious, with his eyes turned inwards, the pupils contracted, hot skin, pulse 116, and in a state of muttering delirium. He was purged, had leeches to the temples, and a turpentine injection. He continued delirious, saying when roused that he had pain in the head. In spite of counter-irritation to the nape of the neck, he became more difficult to rouse, and after becoming cold, and blue, and stertorous, with convulsions, he died on the 30th.

Post-mortem Examination—Thorax and Abdomen.—The lungs were congested and contained scrofulous miliary deposits, and there was slight thickening of the mitral valve-flaps. The renal capsules were adherent to the kidneys. *Cranium.*—The dura-mater was very vascular. The surface of the brain was dry and the convolutions flattened, the ventricles being distended with clear fluid. The septum-lucidum was so softened as to be in a shreddy condition. (97.)

SOFTENING OF THE WALLS OF THE VENTRICLES; PHTHISIS; DISEASE OF THE KIDNEYS; COMA BEFORE DEATH.

Case 99.—Mark B., aged 45, was admitted September 27th, 1854, in a state of phthisis, and with vomiting, and anasarca of the legs, and albuminuria. There was a tendency to hæmorrhage of the gums. He became very low and depressed, and drowsiness without headache came on. He gradually fell into a state of semi-coma, and died October 21st.

Post-mortem Examination—Thorax and Abdomen.—Scrofulous deposits existed in the lungs and recent fibrinous deposits on the edges of the aortic valve-flaps, and the kidneys were much diseased. *Cranium.*—Much fluid existed beneath the arachnoid membrane, and the walls of the ventricles were very softened. (328.)

SOFTENING OF THE SEPTUM-LUCIDUM; EPILEPTIC ATTACKS; DISEASED KIDNEYS.

Case 100.—Charles S., aged 12, was admitted October 20th, 1854, with anasarca, and suppression of urine following scarlet-fever. The urine contained blood and fibrinous casts of the uriniferous tubes. Three days after admission he had an epileptic attack, and on the following day, another. On the 25th much pain in the head was complained of, and he was much flushed. He remained only in a partly-conscious state until he died on Nov. 2nd.

Post-mortem Examination—Thorax and Abdomen.—The lungs and kidneys were much diseased, and the lungs were œdematous, and in places solidified. The ventricles of the heart were dilated, and in the left one much fibrinous clot was adherent to the fleshy columns. The inner surface of the left auricle had in it a rent which appeared to have existed before death. *Cranium.*—The septum-lucidum was decidedly softened, but the other parts of the brain were natural. (340.)

SOFTENING (GENERAL) OF THE BRAIN; DISEASE OF THE KIDNEYS; COMA BEFORE DEATH.

Case 101.—Frederick P., aged 30, was admitted September 13, 1854, in a state of delirium-tremens, and with vomiting and diarrhœa. He had had no sleep for one or two nights. Calomel and opium, with ammoniated salines, were given. On the day following he was so noisy that he was placed in a separate room; he gradually became stupid and comatose, and died on the second day after admission.

Post-mortem Examination—Thorax and Abdomen.—The kidneys had much greyish-white material infiltrated through their texture; there was much ecchymosis of the lining of the stomach, and congestion of the lungs. *Cranium.*—The cerebral veins were congested, and much fluid existed beneath the arachnoid membrane, and in the ventricles. The brain itself, throughout, was softened, and "watery." (291.)

SOFTENING OF THE SEPTUM OF THE VENTRICLES; PHTHISIS; GOUT; DISEASED KIDNEYS.

Case 102.—William J., aged 40, was admitted March

3rd, 1856, in a state of phthisis, and with gout in the hands, and albuminuria. The urine became alkaline, a rambling state of mind came on, he became incoherent and fretful, and at last violent; he died on the 20th.

Post-mortem Examination—Thorax and Abdomen.—There was much scrofulous deposit, and there were vomicæ in the lungs, and the kidneys were very granular. *Cranium.*—The ventricles were full of clear fluid, and the septum of the ventricles was very softened. The brain was otherwise natural. (113.)

SOFTENING OF THE CENTRAL WHITE PARTS OF BRAIN AND SURFACES OF THE VENTRICLES; PHTHISIS; SEMI-COMA BEFORE DEATH.

Case 103.—Elizabeth J., aged 8, was admitted July 23rd, 1856. She had been well until one month previously, when she had dyspnoea and palpitation, and gradually increasing numbness of the hands, with inability to grasp objects; she moaned, was restless, and put the hand to the head. She had also pain in the chest. There was much fever; and moist râles existed in both lungs. Salines and antimony were given; and a blister to the neck, and ice to the scalp, applied. There was no strabismus. The moaning became less, but dozing came on, and the pulse became sharper and more frequent. Eventually, the urine was passed involuntarily, the drowsiness increased, and strabismus came on, and she sank and died four days after admission.

Post-mortem Examination—Thorax.—Scrofulous deposit was found in the lungs. *Cranium.*—The ventricles were dilated by turbid fluid, and the central white parts and surfaces of the ventricles were much softened, the septum-lucidum being quite in a shreddy state.

Microscopic Examination.—The fluid of the ventricles was found to contain flattened and rounded epithelium; pus-like globules; granular matter; remains of nerve-fibres, and cell-forms or vesicles, mostly large and round, and so delicate as to be scarcely visible, some only containing a nucleus, which was small, and situated either in the centre or attached to the cell-wall. (174.)

SOFTENING OF THE CENTRAL WHITE PARTS OF THE BRAIN; FATTY HEART; CONVULSIVE ATTACKS; PARTIAL HEMIPLEGIA.

Case 104.—Pauline W., aged 46, was admitted April 29th, 1857, having had, within the previous three months, two fits, which left her with pain and numbness of the left arm, and occasionally the left leg. There was no disturbance of the equilibrium of the facial muscles. The pulse was weak, the tongue clean and moist. A blister was applied to the neck, and small doses of the bichloride of mercury and sp. æther nitr. were given with a little wine. She went on fairly until May 9th, when she had another fit, attended by struggling, and foaming at the mouth. She remained unconscious afterwards, until she died, May 12th.

Post-mortem Examination—Thorax and Abdomen.—The walls of the heart were thin and weak, and that of the right ventricle, as determined by the microscope, was fatty. There was a small encysted tumour of the uterus. *Cranium.*—Much fluid existed beneath the arachnoid membrane, and in the ventricles. The central white parts of the brain (which was, throughout, very "wet") were softened. (114.)

SOFTENING OF THE CENTRAL WHITE PARTS OF THE BRAIN; CONVULSIVE ATTACKS.

Case 105.—Elizabeth H., married, and aged 24, was admitted June 10th, 1857. She was of a sallow complexion, had had vertigo for one month, and much pain in the back of the head and over the chest. For two days she had rigors, and had spat a little blood and perspired much. On physical examination, nothing wrong was discovered about the lungs and heart, but, on the day after admission she had an epileptic attack, which recurred on the 17th, after which there was ptosis of the left

upper eyelid, and imperfect consciousness, until her death. She lay on her back, frequently sighing, and her left eyelid could not be made to close when touched. She sank and died on the 21st.

Post-mortem Examination.—Cranium.—The bones of the skull were very thin. Much fluid escaped when the brain was removed, and the arachnoid generally was very opaque, at the base of the brain. The lateral ventricles were full of reddish serum. All the central white parts of the brain were very softened, and the fornix and septum-lucidum quite destroyed. Excepting that the capsules of the kidneys were very adherent, the various other organs of the body were natural. (148.)

SOFTENING OF THE CENTRAL WHITE PARTS OF THE BRAIN;
DISEASED LIVER AND KIDNEYS; DELIRIUM TREMENS;
DANCING TORSIONS.
CONVULSIONS.

Case 106.—William T., aged 33, was admitted July 22nd, 1857, in a state of delirium tremens. He had had several "convulsive fits." He died three days after admission.

Post-mortem Examination.—Thorax and Abdomen.—The liver and kidneys were much diseased, and patches of extravasated blood existed beneath the peritoneum. *Cranium.*—Blood-stained fluid existed in the cerebral ventricles, and the central white parts of the brain were in a softened condition. (179.)

SOFTENING OF THE CENTRAL PARTS OF THE BRAIN;
BREAKING DOWN OF THE SEPTUM-LUCIDUM; SCROFULOUS DEPOSIT IN THE LUNG.

Case 107.—Arthur B., aged 15, was admitted April 29th, 1857, having been ill eight weeks with what is termed low fever. He had frequent sickness, coated tongue, weak pulse, and photophobia, with heat of scalp, and constipation. The pupils acted well, and there was no strabismus; the vomiting continued, and pain at the forehead was complained of; he was blistered, and salivated, and treated with iodide of potassium and steel, and cod-liver oil; the pupils became very sluggish, and countenance depressed. The boy became exceedingly emaciated, and lingered on until August 29th, when he died.

Post-mortem Examination.—Cranium.—The skull was large and dense; the brain was "wet," and much fluid existed under the arachnoid and in the lateral ventricles. The septum-lucidum was quite destroyed, and the central parts of the brain softened. *Thorax.*—A slight amount of scrofulous deposit existed in one lung, towards its base, and hepatization existed around. The other organs of the body were natural. (209.)

SOFTENING OF THE SEPTUM-LUCIDUM, CORPORA-STRIATA;
ALSO OF THE MEDULLA OBLONGATA, AND CERVICAL PART OF THE SPINAL CORD.

Case 108.—George G., aged 20, an over-worked teacher in a school, was admitted December 16th, 1857, having for six months been subject to headache. For some weeks pain across the forehead had been very great, as well as giddiness, and intolerance of light. The pupils were much dilated and very sluggish, but equal. The giddiness was not relieved by lying down. In spite of treatment, the dread of light and the pain increased; double vision came on, and much fever. Much relief was obtained from the application of ice to the forehead. The vertigo and dimness of sight increased, and he died December 26th.

Post-mortem Examination.—Cranium.—The walls of the skull were very thin; the cerebral convolutions were much thinned, and the surface of the brain was dry; the ventricles were distended with fluid; the septum-lucidum was quite broken down, and the corpora-striata and thalamio-optici were softened. The medulla oblongata was almost diffuent, and the spinal cord was much softened in the cervical region. *Thorax and Abdomen.*—Excepting some scrofulous deposit in the lungs, all the organs were natural. (300.)

EXTREME SOFTENING OF THE FORNIX; PHTHISIS PULMONALIS.

Case 109.—Alexander McD., was admitted March 17th, 1858, in a state of delirium and unconsciousness. Before Christmas he had been in University College Hospital with fever, stated to be "remittent," from which, it was stated, he had never recovered completely. He suffered from symptoms of phthisis. His pulse was weak and fluttering, and his tongue red. He continued in the same state until he died on the 20th.

Post-mortem Examination.—Thorax and Abdomen.—The lungs contained a large amount of miliary tubercle; and scrofulous deposit existed in the mesenteric glands. The cœcum was much ulcerated. *Cranium.*—The ventricles of the brain were dilated with clear fluid. The fornix was much softened and almost diffuent, but the other parts of the brain presented nothing remarkable. (75.)

SUPPOSED SOFTENING OF THE BRAIN AND SPINAL CORD

Case 110.—Elizabeth C., aged 28, was admitted February 13th, 1858. She was the mother of seven children, who were all healthy, and her family history was good. Her illness began about two years before admission with tingling in half the head, including one-half of the nose and tongue, and subsequently numbness of the right hand came on. The head became all right as to numbness after a time, and so remained, but at the period when the hand became numb great pain was experienced in the head, at the vertex, and a "heavy" feeling, as if she was going to sleep, and this remained. About a year after the right hand became affected, the left one, also, was similarly affected. When first the right hand suffered, it was the thumb and forefinger implicated, feeling as if locked one remaining fingers were affected, and the left hand was affected, all the over another; but when the left hand was affected, all the fingers were simultaneously involved. The feet and legs were affected by general weakness, and it rather appeared as if this weakness had been manifested suddenly. For some months there had been jumpings in the right leg, as well night as day, but rarely during the night. For three months there had been inability to swallow solids. For nine months there had been "mistiness" of sight in the eyes, but there had never been any double vision. Six months ago there was very frequent sickness and vomiting, but this had been absent for five months, relief having been obtained from the use of prussic acid and creasote, with brandy and soda-water. A few months before admission there had also been aching pain at the nape of the neck, but not in any other part of the back, and sometimes the left arm became painful, especially after movement. The patient had never had any convulsive attack, and could assign no cause for her illness. It appeared that mercury had been given to a considerable extent, but that salivation was never induced. On admission she was unable to walk, or even to stand erect, or to sit up in the chair without support. She could move both arms in all directions, but had no sensibility in either hand, so that she could not hold a pin in her fingers unless she saw it. The left arm shook and tottered when lifted up, but not so the right one. She was very intelligent and in excellent spirits. The pupils of both eyes acted, but the left one was decidedly smaller than its fellow, and there was very slight strabismus, but so slight that it was difficult to say which eye was at fault. The muscles of the face were well balanced, and apparently firm and strong. She could distinguish letters, but could not read, owing to a thick mist which came over the words. The sensibility of the skin was in every part unimpaired. She was treated with small doses of the bi-chloride of mercury, and allowed meat diet and porter. Subsequently a seton was placed in the neck. After a month's time she left the hospital very much in the same state as when she entered it, and returned to Devizes, where she was watched by Mr. C. Wayland. That gentleman has kindly informed me that she gradually declined; her articulation became difficult, her memory failed, and she grew almost imbecile. She also became completely

paralysed in all her limbs, and in the bladder and bowels, and was subject to spasm of the throat and muscles of articulation, and died at the latter part of 1861. Unfortunately no post-mortem examination could be obtained, but Mr. Wayland was confirmed in his opinion that she had softening of the brain and spinal cord.

SOFTENING OF THE MIDDLE AND POSTERIOR CEREBRAL LOBES AND THALAMUS OPTICUS ON THE LEFT SIDE; HEMIPLEGIA ON THE RIGHT SIDE; CONVULSIVE ATTACKS.

Case 111.—Archibald B., a married man, aged 23, was admitted November 30th, 1859. He had always been temperate in his habits, and enjoyed good health until six weeks before, when he had a slight rheumatic attack. About two weeks before admission he had got very hot and wet with perspiration in walking, and afterwards became very cold upon the outside of an omnibus, and one week before experienced numbness in the right foot, which gradually extended up the leg, to the side, and right arm. When admitted, there was decided want of power to move the right arm and leg. The facial muscles were natural, but the pupils were rather dilated. The tongue was brown and slightly coated, and protruded to the right. The skin was hot and moist; the pulse 80 and soft, and no pain was complained of. Salines, with small doses of the hydr. c. creta were given, and a blister was applied to the neck. The urine was free from albumen; the pulse subsequently became more frequent, and the gums got affected by the mercury. About the 10th of December, numbness and coldness of the left side were complained of, followed by difficulty in emptying the bladder, and later on the pupil of the right eye was found to be more dilated than its fellow. The stools were passed involuntarily. After that there was a rigor and slight loss of consciousness, following an attack of convulsions of the right arm and right side, which continued for two hours. The loss of power in the arm and leg became more marked, consciousness remained incomplete, and, as he grew weaker, bed-sores formed. In the beginning of January, 1860, a slight amount of albumen was found in the urine, and later on pus-globules were detected. Sordes formed in the mouth; he became unable to protrude the tongue, or to articulate, and a large boil formed on the hand; respiration became very quick, the pupils very small, and much pain was suffered. He died Jan. 17.

Post-mortem Examination.—Cranium.—The greatest part of the middle and posterior lobes of the left cerebral hemisphere, commencing rather above the corpus callosum, and extending almost to the base of the brain, and also of the thalamus-opticus on the left side, were so much softened as to be almost diffluent, and were of a dirty-white colour. The other parts of the brain were natural, excepting that its superficial convolutions were flattened, and that the lateral ventricles were much distended.*

Microscopical Examination showed the softened parts of the brain to contain numbers of granular corpuscles.

Thorax.—The heart was weak and flabby. Some patches of the lung were in a state like the so-called lobular pneumonia. (14.)

THE TREATMENT OF ACUTE ABSCESS OF THE PROSTATE GLAND, POINTING TO THE RECTUM.

By JOHN HAMILTON,

SURGEON TO THE RICHMOND HOSPITAL, AND TO SWIFT'S HOSPITAL FOR LUNATICS.

(Continued from page 614.)

Now, in cases of abscess of the prostate gland, Sir Benjamin Brodie, and a later authority, Mr. Thompson,

recommend it to be opened from the perinæum. Sir B. Brodie says "If such symptoms as I have described exist, and go on for some time increasing, and you discover a fullness and tenderness of the perinæum, do not wait for any more certain indication of the abscess, but introduce a lancet in the direction indicated by the tenderness and swelling. It will often be necessary to pass it quite up to the shoulders, or even to the handle, before you reach the abscess." He recommends this to be done to prevent "it bursting into the urethra," a termination which I have always found in acute abscess to be most satisfactory. Mr. Thompson says* "The incision for this purpose must be made with some boldness, in the median line, in the known direction of the prostate, inclining a little below its situation in the healthy state, since its bulk is chiefly increased in the direction downwards—a fact, however, which is supposed to be perfectly ascertained by the rectal examination." "The depth to which such an incision must be carried cannot be less than an inch and a half, it may be two inches; less than the former will be probably useless, and if so unnecessary and injurious." If the acute abscess does take the very rare direction of the perinæum and makes itself obvious there by swelling and fluctuation, the plain course is to open it in that situation; but I am very opposed to an incision "an inch and a half or two inches deep" in the supposed situation of the matter. It is far preferable, when the abscess points to the urethra (when the presence of the matter is less observable from the rectum), to leave it to break of itself; or where the sufferings demand it, a catheter, either of silver or gum-elastic, with the stilet in, may be passed with a view of its point breaking the abscess, of which I hope to give examples on another occasion. But when fluctuation is discernable at its rectal surface, it should be opened there. The two following cases will exhibit the advantage of this proceeding:—

Case 3.—Mr. A. came to me on the subject of a urinary fistula at the root of the penis, just anterior to the scrotum, the result of an operation for stricture of the urethra performed in California some months previously. A No. 8 catheter was passed into the bladder with some tightness at the seat of the fistula. The operation was fixed for the following week, but it had to be postponed in consequence of his becoming affected with a bad influenza, prevalent at the time. As he lived in the country I did not see him for three weeks. He then came to me complaining of an inflammation in the passage far back. He required opening medicine, which he got; but next day he suffered from much pain far behind in the urethra, and a feeling of weight about the anus and perinæum, and in coming to town the hard seat of the cab and the shaking had increased his suffering. He had frequency and pain in making water. I recognized the symptoms of inflammation of the prostate gland, and felt, through the anus, the gland enlarged, hot, and very tender, so that he cried out when pressure was made on it. Leeches to the perinæum, a warm hip-bath, and small doses of blue pill and extract of hyoscyamus afforded no relief. On the contrary, the pain increased, with a most distressing inclination to go constantly to the night-chair, but when he went he passed nothing. He complained most of this, as along with the inclination, which occurred every ten minutes, there was a great deal of painful spasm—perhaps one of the most distressing of the symptoms of acute inflammation of the prostate. On passing the finger, I found the tumefaction of the gland much increased, with the soft feel of fluctuation in the left lobe, but the matter as yet was not near the surface of the gland. As he passed water each time he went to the night-chair, it could not be said whether there was the usual irritability of micturition, and as the quantity was so small each time, the stream could not be ascertained; the water was clear.

Two days after the symptoms were just as bad, but I thought it likely that the matter would be more advanced

* The softened brain is described in the Hosp. Pat. Cat., series viii., No. 51.

* The Enlarged Prostate, p. 206.

to the rectal surface of the prostate, and that I could relieve him by letting it out. Accordingly, I found fluctuation very apparent, the part soft, and more extended to the other side, and a spasm coming on I felt it become quite tense. I therefore passed a sheathed bistoury on my finger through the anus till the end rested on the centre of the abscess, which I opened by exposing the sharp end and plunging it in. At once, about two ounces of healthy pus, mixed with a little blood, came from the anus.

He got immediate ease. Two hours after he passed three table-spoonfuls of matter. At bed-time a tepid water enema was administered. The next day his brother called on me and told me that he had slept soundly and felt perfectly well. He came to town himself at the end of a week looking very well, no irritation in the rectum; but he told me that three days after I saw him he had frequent desire to pass water with some pain. A gush of matter came with the water from the urethra with great relief, but he still has a little irritability in making water. A few days after he went on a visit to some friends in the country, and I got a letter from him at the end of three weeks saying he was, as far as the abscess of the prostate went, perfectly well.

Case 4.—A delicate-looking young man came to the hospital (February, 1865) complaining bitterly of pain in the fundament and difficulty and pain in making water. He had had gonorrhœa for several weeks; the discharge declined, but some days before admission the violent pain behind began. There was no appearance of anything wrong about the outside of the anus, but when I introduced my finger (not without difficulty from the spasm of the sphincter and the pain it gave) I felt a considerable enlargement and induration of the left half of the prostate, exquisitely sensitive on pressure. Some leeches were applied to the perineum, he got a warm hip-bath and some aperient medicine. The inflammation was so intense and had lasted so many days, that I had no hope of preventing suppuration, but merely expected to give some relief to the pain. I did so, but to-day, the fourth after admission, though he did not suffer quite so much pain, he could not pass water, and when I examined by the anus, the hard tumefaction of the prostate had become soft and evidently contained fluid. I therefore determined to open the abscess of the prostate through the anus. I accordingly prepared a curved sharp bistoury by rolling a narrow piece of lint round it to within a quarter of an inch of the end, so as to cover the sharp edge, and protect the side of the anus from it. I next fixed a small ball of wax on the sharp extremity. Thus guarded and well oiled I passed it along my finger till its point touched the soft centre of the tumour, when I pushed it on through the ball of wax into the abscess. About two ounces of yellow pus escaped from the anus. Immediate ease followed.

Two days after he was remarkably relieved, passing water well and suffering only from slight soreness of the lower end of rectum. There was a slight return of the gonorrhœal discharge, but a fortnight after he left the hospital quite well.

NORTH CHARITABLE INFIRMARY AND CITY OF CORK GENERAL HOSPITAL.

CLINICAL LECTURE.

By Mr. SHINKWIN,

JUNIOR SURGEON TO THE HOSPITAL, AND DEMONSTRATOR OF ANATOMY,
QUEEN'S COLLEGE, CORK.

GENTLEMEN,—As we have had some cases of fracture of the upper extremity under our observation for the past four weeks, I take this opportunity of directing your attention to them more specially than I possibly could do in a ward full of patients, who watch with the utmost anxiety every word that may drop from us as we speak by the bedside.

The cases I allude to were, you may remember—first, oblique fracture of humerus, at its inferior third; second, fracture of clavicle, about an inch and a half from its acromial end; third, that peculiar fracture of the lower portion of radius, called after the person who first described it, Colli's.

It is not my intention to speak of fractures of the humerus, or of the clavicle, or of the radius, as such. This class of teaching I look on as distinct and separate from clinical instruction. It comes more within the sphere of your "Professor of Surgery;" he generalizes and takes in the whole "Art and Science of Surgery," whilst we, as clinical teachers, have only to speak of the actual cases under our care.

The case of fracture of the humerus was the first bed we used to stop at in No. 1 Ward.

Mr. Mowle, our Clinical Clerk, gives the following history of this case:—"Whilst the man was driving a cart along one of the quays the horse became so restive and unmanageable that he ran the car against a wall; the man, sitting on the side of the vehicle nearest the wall, tried to save himself by jumping off, but before he could accomplish the act he was caught between the wall and shaft, and had his arm broken, and also received some bruises of his side.

On his admission it was at once apparent that there was injury done to his arm, as the deformity was very marked, the fracture being oblique. This direction of fracture, I need hardly tell you, is more favourable to displacement than had it been a transverse one, and also made it more difficult to keep the parts in apposition. In the first instance, the bones have surfaces which easily glide one over the other, whilst in the latter, when once the bones are properly placed and splints applied there is no fear of displacement; and now to describe the treatment adopted.

When we reduced or set the fracture—that is, when we brought the ends of the bones together, by using a good deal of extension and by keeping the forearm flexed on the arm, the entire limb was nicely and evenly bandaged from the fingers up to the shoulder. A well-padded angular splint was then applied on the outer side of the entire limb, whilst a straight one was laid on the inner side of the arm, and the entire bandaged with a roller. The arm was then placed in a sling, and a few turns of bandage applied round it and the thorax, by which means the whole arm was firmly secured to the body, and rendered perfectly immovable. This plan of treatment had, I am sure, a good deal to do with the quick recovery the patient made.

Four or five days after the occurrence of the injury we had to loosen the bandage on forearm, as there was great swelling near the elbow. In about seven or eight days the angular splint was removed, and in its stead we placed two short splints, one on the outer, the other on the inner side of arm. Just at this period of the case the patient complained of cough and some dyspnoea, and on examining his chest we found that he had an attack of bronchitis at the injured side. This was quickly subdued by the usual treatment.

For the past eight or ten days Driscoll's arm has been kept in pasteboard splints, firmly bandaged with a roller made stiff by a mixture of prepared chalk and gum. This apparatus, nicely applied by Mr. Mowle, has kept the parts in close apposition, and on cutting open the bandage and splints (just alluded to) a few days ago, we found the fracture perfectly united, with, I may say, hardly any deformity. The splints and bandage retaining the shape of the arm were re-applied, and the man dismissed after being three weeks in hospital.

If a case, similar to the one I have just described, should come under your care, and that you carry out the same plan of treatment we adopted, I am sure you will have success. It is a class of fracture easily diagnosed, and with common attention quickly cured. I think for the first week or so the angular splint is the best to apply,

as it gives more general firmness to the limb than any other, but after that time I would fear that leaving it on would give the patient unnecessary trouble. After the lapse of a week all spasm of the muscles is subdued, the parts have become accustomed, if I may so speak, to their new position, and the plain long splint, the outer one, reaching a little above the shoulder, and below the elbow, the inner nicely and evenly padded, care taken that it should not excoriate the axilla, will answer all the purposes of the angular splint, and give your patient great freedom of action in the wrist and fingers.

Dr. Sutton, of Warwickshire, in THE MEDICAL PRESS AND CIRCULAR of the 24th October, speaks in the highest terms of what he calls a cylindrical splint. He states that he applied it in a case of oblique fracture of the arm, and that he never removed it from the day of its application until he did so finally. This in all fractures is a great desideratum, and should we have an opportunity we will try how this splint will work. One grand principle you must always bear in mind; that in fractures of the humerus you must keep the elbow flexed; if you do not the muscles attached to the broken ends of the bones will be in continued spasm. "Both patient and surgeon," says Percival Pott, "concur in putting the arm in the flexed position—that is, into such a state as relaxes all the muscles surrounding the broken bones," such, then, is my advice to you with regard to the treatment of fractures of the lower third of the humerus. Acting so you will be carrying out the three great principles to be adopted in the treatment of all fractures—1st. By relaxation of the muscles consequent on flexion of the elbow, you are able to adjust the bones properly. That effected—2nd. You retain them in their proper position, steadying the whole limb with the angular splint; and 3rd. By substituting the plain splints and immovable apparatus, you prevent any subsequent annoyance, such as stiffness of elbow, or immobility of fingers.

Our second case was that of a jingle driver, who, whilst driving, was thrown off his seat, and falling on the left shoulder, fractured the clavicle about two inches from its acromion end.

On admission he was so tipsy that at first we hardly knew what was the matter, but after a careful manipulation of left shoulder, we were satisfied that there was a lesion of the bone in the situation I just mentioned. As we ran the fingers over the bone, the separation was immediately perceived, for the outer fragment was considerably lower than the inner, and slightly overlapped by it. I need hardly remark that this displacement can be accounted for in two ways—1st, by the weight of the arm pulling the outer fragment down, it being totally separated from its support, and also, by the action of the deltoid fibres, whilst the inner end of the bone is more or less fixed by the pectoralis major on one border, and the clavicular attachment of sterno-cleido mastoid on the other. I have here before me notes taken from Robert Smith's book on fractures, written indeed when I little dreamed that I should be a clinical teacher in this hospital, or that I should ever make use of them in a lecture; it was my intention to have read his description of this fracture for you, but time will not permit me; get the book for yourselves—read it—study it well, and its perusal will be of incalculable benefit to you.

The position this patient assumed in bed was peculiarly characteristic of the accident. He sat with his head yielding to the left side, the arm supported by the right hand placed under the elbow. If a patient comes to you in this attitude, make a careful examination, as you may rest assured something is wrong at or about the shoulder. In the treatment of this case we had two difficulties to overcome—to bring the ends of the bone together, and then to retain them in position. To accomplish this was not at all as easy as you might imagine; an assistant placed his hand in the axilla, thereby making a fixed point, the shoulder was then drawn backwards and outwards; by acting in this way, the external fragment was brought from its position under the inner one, and then, by

lifting up the elbow, we had the ends of the bones pretty fairly placed *in situ*. To keep them so was then the question; this difficult feat was undertaken by Mr. Barry; he made a large tow pad and rolled it up in a piece of calico long enough to tie over the opposite shoulder; this he placed in the axilla, and firmly fixed it in the manner just mentioned; he then by means of a good broad bandage firmly placed the arm to the side, giving a few turns of the roller, from under the elbow over the fractured clavicle, thus exercising a certain amount of pressure on the clavicle, by which means he kept the bones level, and formed a sling for the arm. This is most essential; indeed when putting up such a fracture I always try and dispose my bandages so as not to require a shoulder strap at all, and form by them a regular socket for the elbow, but I must acknowledge by doing so, you oblige your patient to keep his arm with the hand nearly touching the shoulder of the opposite side—not as convenient a position as the one permitted to this man.

I cannot speak too highly of Mr. Barry's care to this case—one day loosening and another tightening the bandages, as they fretted the patient's skin and temper, the latter by no means a good one, or became so disarranged as not to fulfil the object of the dresser. However, all difficulties were overcome, and the man was dismissed perfectly cured, after being four weeks in hospital.

The third and last case we have to consider is that of an old lady who, do what we could with her—watch her as closely as we might—used to take the greatest possible delight in undoing whatever we did. She was the most restless patient I ever had under my care. Dresser and nurse, house-surgeon and surgeon, did all they could to send her out a credit to the hospital, but all our attention availed nothing. The perversity of the sex was too firmly ingrafted to be so lightly laid aside, and the result was that she left hospital with a deformed arm. Splints were applied; next morning they were found under her pillows. Nurses were threatened to be fined, and the splints put on again; it was no use. Temper—that is, a good one—is a great blessing; but even Collis himself would have lost his had he had this woman under his care.

The accident in her case was a very perfect specimen of fracture of the radius, say about an inch above its carpal end, and would not have been so easily diagnosed but for the peculiar appearance the arm presented; for I cannot agree with Erichsen when he says "there will be noticed crepitus on rotating the bone whilst the hand is drawn down." We would rather incline to Robert Smith's opinion, that there is an absence of crepitus in such cases, and that the swelling makes it a very difficult fracture to diagnose. This swelling is usually on the dorsal aspect of the limb, causing a considerable deformity, whilst on the anterior part of the arm there is great fullness, as if effusion had taken place under the flexor tendons. This fullness will not extend in ordinary cases beyond the annular ligament, nor higher up than about a third of the arm.

The best way for you to examine a case where you suspect such a fracture to exist is to apply the fingers of one hand to the seat of the suspected fracture, and then locking that of the other hand in the person who is suffering, to make considerable extension, at the same time keeping the hand of the patient bent. By doing so, if there be fracture you reduce the swelling both on the palmar and dorsal surface, the latter caused by the carpal extremity of the radius being directed upwards and backwards, not downwards, which is its normal aspect; and as the carpal bones are firmly united to the lower end of the radius, they must follow, and in this way we have the tumour on the dorsal aspect of the hand; whilst the former, that is, the palmar tumour, is produced by the radius being drawn backwards, causing the ulna to appear more prominent towards the palmar surface of the wrist; or by "the projection forwards of the lower end of the upper fragment being put into a state of forcible pronation." These symptoms disappearing, and mobility being present, you may conclude that there is fracture.

In this case our treatment was most unsuccessful. The splint we used was the one recommended by Gordon in the *Dublin Quarterly Journal*; but I think no matter what apparatus was put on, the patient would not permit it to remain, and we were obliged to permit her to leave the hospital a disgrace to our surgery and our infirmary.

Hospital Reports.

MERCER'S HOSPITAL.

MEDICAL WARDS.

CLINICAL REMARKS: WITH CASES.

By WILLIAM MOORE, M.D. Dub., M.R.I.A.,

SENIOR PHYSICIAN TO MERCER'S HOSPITAL; VICE-PRESIDENT OF THE COLLEGE OF PHYSICIANS, AND LECTURER ON THE PRACTICE OF MEDICINE, &c.

(Continued from page 618.)

"ANEURISM OF ASCENDING AORTA."

(Reported by Mr. H. T. BROWNIGG.)

Case 2.—James M., aged 42, a porter by trade, was admitted into this hospital on the 30th June last. Both his father and mother are dead. He has one brother and three sisters alive and well. He served as a soldier in the East India Company's service for nineteen years, when he was sent home invalided. A few days previous to his admission into hospital he was removing rain water from the balcony of a house in this city when he suddenly felt "all the blood rush to his head" (as he described it), became giddy, and fell. When we first saw him his face was livid and swollen; the angle of the mouth on the left side was drawn slightly downwards; the neck was swollen and tender on pressure; the jugular veins standing out prominently; the pupils were unaltered; he complained of deafness of his left ear; the right upper half of the body and the right arm was cedematous. There was a patch of ecchymosis about the eighth rib, probably the result of the fall, and on running the hand over the chest, a slight general prominence could be felt at the upper part and the right side, about the junction of the second and third ribs with the sternum. Now, the subjective symptoms this patient chiefly complained of were dyspnoea, amounting at times to orthopnoea, of dysphagia, of partial loss of vision, and of giddiness on assuming the erect position. His voice was peculiarly hoarse and laryngeal; this hoarseness supervened on the accident, as he stated that he never had loss of voice at any previous period. His cough was ringing and brassy, and the expectoration of the consistence of thin gum water, and of a rusty colour. On percussion there was appreciable dulness over the prominence at the right side of the chest, and here a faint single systolic bruit was audible. The respiration in the right lung was deficient, that of the left puerile; the pulse at the right wrist was scarcely perceptible, whilst that of the left was normal. He suffered from severe neuralgic pain down the right arm and over the right side of the chest generally. To relieve the distressing dyspnoea we tried ether, chloroform, lobelia, and other remedies without avail, whilst anodyne liniments were simultaneously used for the relief of the violent neuralgic seizures. After the lapse of a fortnight this patient went home, and after being some days there, and his symptoms becoming still more urgent, he applied for admission into the Meath Hospital. Here he was followed by Dr. Brownrigg, who (with zeal which does him great credit), was determined to see the sequel of the case. This opportunity was soon afforded him, for on the 2nd of August it proved fatal, when a post-mortem examination revealed a large tubular aneurism of the ascending portion of the aortic arch, which, if distended, would have contained a pint of fluid. There was no rupture of the sac, which was partly

filled with fibrine. The right lung was collapsed, and the right pleura generally was adherent, whilst the left lung seemed healthy. About five pints of bloody serum was found in the right pleural cavity.

Now, in this case the collateral symptoms, so to speak—viz., dyspnoea, dysphagia, partial aphonia, neuralgic pains, laryngeal cough, the comparative absence of respiration in one lung, the inequality in the radial pulses, coupled with œdema, hæmoptysis, and other objective signs of arrested circulation—mainly contributed to the diagnosis. No doubt percussion gave us some aid, and the stethoscope elicited a faint systolic bruit, heard over a circumscribed region; still in many cases of this too frequently latent malady all stethoscopic evidence is negative or altogether absent, and then you must fall back on the collateral symptoms, more especially those due to nervous pressure, as reflected on the eye and its appendages, in variations in temperature, and in cutaneous eruptions, in addition to the other symptoms already mentioned.

As regards the treatment of this terrible malady, it generally consists in relieving the symptoms as far as in us lie, more than in bringing about any radical cure. Years ago Valsalva recommended general bleeding, which, I need scarcely add, has been exploded, and in its stead purgatives and diuretics have been employed with the view of diminishing the watery constituents, whilst sedatives, as digitalis, hydrocyanic acid, acetate of lead, and other such remedies are exhibited with the view of lessening the heart's action, and thus bringing about coagulation in the sac; locally, ice and cold applications have been applied with the same intent. Iodide of potassium has been strongly recommended by Dr. Roberts, but my own experience of this remedy in aneurism is not sufficiently extensive to express an opinion on its merits. Should angina or symptoms of weak heart complicate the disease, the diet must be somewhat stimulating.

The third and last case to which I shall call your attention on the present occasion is one of "Paralysis from Lead Poisoning," which Mr. Gregory Sale has kindly furnished us with the notes of:—

Case 3.—John H., aged 47, was recently admitted into this hospital, when he appeared anæmic, wasted, and generally paralytic. On closer examination, we found the capsular muscles of the right arm much atrophied, especially the deltoid and supra and infra-spinati, latissimus dorsi, and serratus magnus of the same side. The extensors of both forearms were comparatively intact, but "paralysis agitans" was well marked, more particularly in the right arm. The blue line was visible around the base of the teeth, which were covered with the black discolouration. The heart's action was feeble; he complained of deafness, of giddiness, and occasionally of inability to speak for a few minutes. He has suffered from repeated attacks of colic, and his bowels are habitually costive. Pulse 78.

Now, at first sight you would not think there was any feature of unusual interest in this case, but a little further reflection will show you that it does possess some features not the rule in cases of lead poisoning. In cases of paralysis from lead we usually find the extensors of the upper extremities principally affected. In this case these muscles may be said to have been intact, whilst the muscles of the upper arms and scapula were much atrophied, especially on the right side; but, even here, the atrophic symmetry was not preserved, as the biceps and coraco brachialis were of almost normal calibre; but let muscular atrophy exist where it may associated with lead poisoning, my experience leads me to conclude that the spinati muscles of the scapula are sure to suffer.

Now, about the treatment of this form of disease: In the acute stage, taking the hint from Briquet, we have applied electricity through the medium of damp sponges over the abdomen, and with good effect in relieving the acute pain, following up this application with a brisk purgative and the warm bath, and when the bowels have been well relieved, the exhibition of iodide of potassium

in doses of from five to ten grains three or four times a day. You are aware Mr. Melsens has strongly recommended this remedy for the elimination of lead, and Dr. Parkes has given proof of the lead passing off by the kidney during the exhibition of this iodide. Strychnine, where much loss of power is present, is a valuable adjunct to the iodide of potassium, in doses varying from one-twentieth to one-twelfth of a grain, which may be gradually increased. Simultaneously baths should be employed, more particularly that containing sulphuret of potassium (about four ounces of the sulphuret to the bath), in which the patient should remain for twenty minutes or half an hour; and, for the relief of the neuralgic pains, the compound camphor or soap liniments, with chloroform, aconite, belladonna, or opium, will be found efficacious, whilst electricity should be daily employed till all loss of mobility has disappeared.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS,

DR. LYONS'S CLINIQUE.

ABSCESS OF THE LIVER; PUNCTURE OF THAT ORGAN.

(From Notes by Mr. J. A. CLARK, Clinical Clerk.)

JOHN REHILL, aged 39, a labourer, engaged in the construction of sewers under the Engineering Department of the Dublin Corporation, was admitted into the Whitworth Hospital, and placed under Dr. Lyons's care on the 14th August, 1866. He had generally enjoyed pretty good health until three years previously, when he suffered from a slight attack of jaundice, which appears to have lasted not more than ten days. Subsequently to this he states that he continued in good health till April in the present year. He then began to experience a sense of weakness after taking food, with frequent pyrosis. For some weeks he vomited occasionally after his meals—usually at an interval of two hours. On the 29th July he threw up a quart of green and yellow stuff. On admission he had a remarkably cachectic appearance, with a sallow hue of the surface generally. The tongue was foul, a sense of nausea was experienced, but there was no vomiting, and the pulse was under 60. His principal suffering was referred to the epigastric and left hypochondriac regions, with occasionally severe pain in the back. On careful examination in this situation a marked fulness was observed in the scrobiculus cordis, and pressure, however slight, in this region gave him intolerable distress. He complained much of want of sleep, and had distaste for food; he suffered much from flatulence, and his bowels for weeks together were not moved except under the stimulus of enemata and active purgatives.

On the second day after admission his pulse was noted at 50, the next day it was 60, and two days subsequently but 48. It was henceforth very variable, but usually ranged between 40 and 60, and on one occasion fell so low as 38. The action of the heart demands notice; it was slow and labouring, especially when incommenced by the extreme flatulent distension of the stomach, which was of frequent occurrence. Occasionally the heart presented a most distinct and regularly recurring triple rhythm.

On numerous occasions a very distinct pulsatile wave was observable in the epigastric region, and a throbbing sensation was constantly experienced by the patient himself. As week after week passed by the sufferings of this truly patient creature increased. The tumefaction within the area of the costal arch became more and more prominent, very strong pulsation was frequently found in it, and the pain inflicted by the gentlest pressure in daily exploration was all but intolerable; he could only lie in a peculiar semi-diagonal position on the left side. Violent "stabbing" pains were now frequently experienced, and

on the 20th October, more than two months after admission, from twelve in the day till near midnight, he suffered terrific agony, and complained of excessive suffering from the epigastric pulsation. The sense of thrusting forward of the sternum was agonising to the patient; he said repeatedly he felt as if he should burst open, and on one occasion his suffering was so intolerable that he had to be held down in the bed, and nothing but chloroform inhalation to partial insensibility gave him any relief. To the clinical clerks who, through his long period of suffering, paid such unremitting attention to this patient, Dr. Lyons tenders his most grateful thanks. His pulse, which on the previous day was but 40, rose at 10.30 to 120, but in a day or so fell to its usual range, between 40 and 50. About this period a new feature was added to the case—he began to sweat at night, and on some occasions to a profuse degree. Chill or rigor was at no time observed, though carefully inquired for.

Passing in review all the possible conditions capable of being brought to explain the phenomena presented in this remarkable case, Dr. Lyons came to the decided opinion, *par voie d'exclusion*, that an abscess of the liver, occupying probably the left lobe, could alone satisfy the requirements of diagnosis.

Having regard to the pulsation so forcibly present at intervals, and the pain in the back, the possibility would naturally occur to the mind that the case might be one of abdominal aneurism, thrusting before it the left lobe of the liver. The absence of diastolic throb, and of murmur, as well as of any persistent and boring character in the pain, taken in connection with the sweats, slow pulse, and other features of the case, made conclusively against this view.

Dr. Lyons having had frequent consultations with his immediate colleagues, and having further enjoyed the advantage of Sir Dominic Corrigan's assistance in consultation, came to the decision to explore the tumour by incision and puncture, and should circumstances seem to admit or demand it, to evacuate its contents, if any.

The patient's state was such that he not alone readily lent himself to the proposal for an operation, but such were the effects upon him of his protracted and increasing sufferings that he urgently entreated that something should be done even to attempt to afford him relief. Leeching, blisters, poultices, and the full and continued use of morphia in half-grain doses, every four or six hours, had failed to bring about the slightest permanent amendment. The patient's remaining strength was fast giving way under such continuous pain, distress, and occasionally positive agony as he experienced, and unless mechanical relief could be procured in some way, his death was to be anticipated at no distant day. Indeed, for many days Dr. Lyons's first inquiry of his clinical clerk at the hour of morning visit was whether Rehill was still alive. Surely such a state of things warranted some bold procedure, even with but a faint hope of success.

On the morning of the 2nd November, the pulse being 72, an incision about two inches in length was carefully made at eleven A.M. over the most prominent part of the swelling. The peritoneum was readily reached, and was found to be non-adherent. A fine trochar was passed into the liver, but nothing save a couple of drachms of dark hepatic blood, contrasting forcibly with the vivid colour of the blood in the subcutaneous section, was withdrawn. It became evident that the abscess, of the presence of which Dr. Lyons entertains no doubt whatever, lay a little to the right or left of the puncture, and that further procedure was for that day out of the question. The external wound was kept open by a pledget of lint, a poultice was applied over the part, an opiate administered, and the most perfect rest enjoined.

At three o'clock P.M. the pulse had fallen to 52, and what it is most strange to relate, the patient expressed himself improved to a degree that exceeded all expectation, and which was out of all proportion to the amount of mechanical relief which could be supposed to be due to

the removal of the tension of the parietes of the abdomen, and the abstraction of the few drachms of hepatic blood which escaped by the trochar.

Each day now found the patient better and better; no threatening of peritoneal or hepatic inflammation followed the incision and puncture of the liver. The epigastric tumefaction sensibly increased, and it became evident that an effort was being made for the abscess to come to the surface, and a well-marked mountainous elevation, some six inches in diameter at the base, now occupied the site of the costal arch. Even those who had been previously sceptical as to the nature of the case were now prepared to admit that "it was now something like an abscess coming to the surface." At this period the patient began to sweat most copiously by day as well as by night; a profuse general hydrosis covered the whole body, requiring his clothes to be changed on many nights. Coincident with this new phenomenon the epigastric swelling daily diminished; all remaining tenderness gradually subsided; the patient began to recover spirits, appetite, and strength, and slept with tranquillity. In less than a fortnight after the operation he was enabled to sit up and walk about the ward. The bowels were still obstinately constipated, and flatulent distension of the stomach and abdomen generally were constantly complained of. While sitting at the fire on the 19th November, he was seized with most violent abdominal pain, and became completely prostrated, requiring to be carried to bed. The pulse did not rise above 66, but as there was much desire to vomit, with great abdominal distress, the hopes of his recovery were for a time rudely dashed. More careful exploration, however, satisfied Dr. Lyons that he was labouring under nothing worse than an unusually severe fit of colic. Appropriate remedies were prescribed, and the patient again resumed his steady progress to convalescence. The pulse ranged from 60 to 70; the heart's action became regular; appetite and strength gradually returned; sleep, full, long, and refreshing, was enjoyed without morphia, and natural action of the bowels was restored, without purgatives, after many months of obstinate constipation.

All sense of uneasiness over the liver disappeared, free and supple motion of the trunk was restored, and in about five weeks after the operation the patient left hospital to resume his avocations in the lighter and less trying occupation of a day watchman. He was seen last on December 19, 1866, his pulse was 76, his general state much improved, and he was entirely free from all gastric or hepatic uneasiness. His illness had lasted about nine months.

In commenting on this case, Dr. Lyons asks, if not an abscess of the liver, what was it?

That it was such he is fully convinced, and he further concludes that, so far as the experience of a single case goes, it may be taken in conjunction with others to show that—

1. Puncturing of the liver for the relief of abscess, when such a morbid state is presumably present, may be performed with immunity.
2. That even should the abscess be not reached, puncture of the liver stimulates that organ to active absorption, and that then an abscess may be absorbed by the natural efforts stimulated by art.
3. That when a fair presumption of an abscess in the liver exists, the sooner an operation for its possible relief is undertaken the better, as it is highly probable that in such a vascular organ the presence of one centre of purulent transformation acts as a source of infection to other parts of the organ, and induces multiple abscesses.

The copious sweats were in all probability the mode of vicarious excretion selected by nature for the removal of the purulent matter in the case above recorded.

The case has two important interests:—1. It is an example of recovery after a very protracted and very painful illness. 2. It is an ample theme for discussion.

Reviews.

CHROMO-LITHOGRAPHS OF THE DISEASES OF THE SKIN. By ALEX. BALMANNO SQUIRE, M.B.Lond. London: Churchill and Sons. 1866.

THE profession are tolerably well acquainted with the coloured photographs originally issued by Mr. Squire. The plates now under notice are re-publications of these in a cheaper form than that in which they were at first issued; and thus they are now accessible to every student of cutaneous diseases. The portraits are good—very good—and each is typical of a separate class of disease.

Some will, perhaps, say that portraits of diseases of the skin ought to be of life size; and were expense and convenience not to be taken into account, they undoubtedly ought; but yet, for the purpose aimed at by this publication, the success is complete, and the letter-press accompanying each plate is a valuable addition to the usefulness of the entire set.

To those who have, or who may have, these chromo-lithographs, we would suggest that the letter-press respecting each class should be inserted opposite to the plate to which it belongs, as in that case the student's labours will be much facilitated. In Mr. Squire's collection we have portraits as follow:—Psoriasis (diffusa); Impetigo (figurata); Lichen (inveteratus); Scabies; Chloasma; Favus; Lupus; Papular Syphilide; Nævus (vascularis); Erythema (tuberculatum); Eczema; Pemphigus.

In the letter-press, we find in each class:—*a*, a general description of the disease; *b*, its treatment; *c*, the history of the case exhibited in the portrait, pointing out its most noteworthy points.

It is to be hoped that Mr. Squire will not stop here, but continue the production of chromo-lithographs, such as we now have great pleasure in recommending to our readers.

EDINBURGH MEDICAL JOURNAL. December, 1866.

THIS number contains five original communications:—1. On some of the therapeutic effects of Bromide of Potassium, by Dr. James Begbie; 2. Cases of Ovariectomy, by Mr. Keith; 3. On the Management of the Second Stage of Natural Labour, by Dr. Hardie of Manchester; 4. On the Pathology of Cholera Collapse, by Dr. Horace Jeaffreson of London; and 5. The concluding portion of Professor Struthers' Historical Sketch of the Edinburgh Anatomical School. All these articles are good; but the first and last are specially so.

THE GLASGOW MEDICAL JOURNAL. New Series. December, 1866.

THERE are two original papers in this number:—One, the Introductory Address at the Public Opening of the Medical Session, 1866-67, by Professor Gairdner; and the other, "Remarks on Alcohol," by David Pride, M.D. There is also a Clinical Record, by Dr. Grainger Stewart, with some reviews, and other medical matter. Dr. Pride's paper deals with alcohol in its bearings upon digestion; as a heat-evolving agent; and as a nerve stimulant when prescribed in a medicinal form. His doctrine seems to recommend the use of alcohol only in extreme cases; according to his own rendering of the proverb of the wisest of kings:—"Give strong drink unto him that is ready to perish."

ATLAS OF PORTRAITS OF DISEASES OF THE SKIN, issued by the New Sydenham Society. Sixth Fasciculus, 1866.

THE present issue contains three plates.

Portrait xv. represents eczema impetiginodes on the face of an adult. Portrait xvi. represents eczema on the face of an infant; and also eczema rubrum on the leg of an adult. Portrait xvii. is rather extensive in its details, representing several distinct affections—namely, psoriasis of the hands and finger-nails; syphilitic psoriasis of the finger-nails; congenito syphilitic psoriasis of the finger and toe-nails; onychia maligna, and chronic general onychitis. It is scarcely necessary to say that these portraits are quite as good as their predecessors; indeed, portrait xvi. is one of the best, if not the best, of the whole series.

TEMPERATURE IN ACUTE DISEASE. Being a Thesis read for the Degree of Doctor in Medicine before the University of Dublin, June 26th, 1866, by Thomas Armetriding Compton, M.D. Dub.; B.A. of Corpus Christi College, Cambridge. 8vo. London. 1866. Churchill and Sons.

This pamphlet of 81 pages 8vo, originally appeared in the August number of our cotemporary, the *Quarterly Journal*, and is now published as a second edition, in a separate and revised form.

Among the alterations which it has undergone since its first appearance we notice the abolition of the tables inserted in the first edition; and the substitution for them of elaborate *diagrams*, printed from letter-press, by Mr. Falconer of Dublin. This system of printing diagrams in letter-press is somewhat novel, and is likely to prove of great use to the profession, now that the thermometer is fast becoming as necessary to the physician as is the stethoscope.

NOTES ON ANIMAL MECHANICS. By the Rev. Samuel Haughton, M.D., Fellow of Trinity College, Dublin. [Pamphlet.]

THESE notes were read before the Royal Irish Academy, on the 26th of June, 1865, and are reprinted from the Transactions of that learned body.

It is not necessary for us to recommend anything from the pen of Professor Haughton; and in the present instance it is least of all required, because it is understood that the rev. gentleman is preparing an elaborate work, an *opus magnum*, on the important subject of animal mechanics. It is, however, a matter for congratulation that questions like this, which are so intimately bound up with our profession, should be brought before so important and influential a body as the Royal Irish Academy.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 26, 1866.

THE NATURAL SCIENCE TRIPOS AT CAMBRIDGE.

ALL those who are interested in the progress of Natural Science must feel gratified at the manner in which it is now encouraged in the two most ancient Universities of England, and the result of the examination just concluded at Cambridge for the Natural Science Tripos is alike honourable to those who conducted it, and to those who have succeeded in passing the ordeal. To those who are unacquainted with the system recently introduced into the Cambridge examinations for members of the Medical Profession, it may be as well to state that not only are great facilities now offered to the student for making himself proficient in the different studies connected with medicine, but the modes of proceeding adopted for graduating in medicine and surgery have been of late years materially modified and improved. That very much merit is due to the indefatigable exertions of Dr. HUMPHRY, the present Professor of Anatomy in the University, and Surgeon to Addenbrooke's Hospital, it would be most ungracious and ungrateful to deny, and his efforts have been in many cases warmly and liberally seconded by the authorities who hold the purse-strings, and by whose permission and under whose

auspices this really magnificent new hospital has been erected, together with the new chemical laboratory, the new museums of anatomy and comparative anatomy, the dissecting-room, and the other appliances necessary in a first-rate medical school. That much effort was required to overcome the *vis inertia* of a system which had grown hoary with antiquity will readily be believed; and even the shades of LÖCKE and of Sir ISAAC NEWTON, to mention none of the series of illustrious divines, classical scholars, and mathematicians, who have adorned this ancient seat of learning, may well have been astonished if they ever re-visited this earthly scene, at the introduction of modern science as an integral part of the curriculum of the University. The two first-named philosophers indeed would, no doubt, have encouraged such a movement, but their contemporaries and successors were in general so well satisfied with things as they were, that until very recent times the fundamental truths of the great practical sciences which are now effecting a moral revolution of the world, were taught almost everywhere *except* at the two old Universities.

Times, however, are now altered, and Cambridge, so far from lagging in the rear in the march of improvement, is boldly advancing in the front ranks. Some of its Museums, especially those of Mineralogy and Geology (the latter under the auspices of the veteran and accomplished Professor Sedgwick), have long been among the finest in the world, and now those of Human and Comparative Anatomy are already rivalling some of the best collections in the large cities of Europe. While the study of Classics and Mathematics is still pursued as keenly as ever, and while those subjects still form, as they ought to do, integral parts of all the examinations, yet they are supplemented by the modern pursuits of Chemistry, Comparative Anatomy, Botany, Geology, and Physiology, and proficiency in these departments ensures an equal rank with that in the Ancient Languages and in Mathematics.

The Natural Science Tripos, the examinations for which have just concluded, is often selected by the Medical Students, and most of the subjects embraced in it are those which are in close alliance with Medicine, so that in passing in this Tripos the student is actually gaining a step in his medical curriculum.

The Tripos questions have been published, and we are struck by the very great improvement which they manifest in comparison with those of former years. It cannot be denied that on previous occasions the questions, especially those in Physiology and Comparative Anatomy, were not in all cases judiciously selected; but in the present instance no such fault can be found, as they are admirably put together, and are both clear in expression and comprehensive in their scope, and well adapted, in every respect, to elicit the knowledge of the industrious student.

QUACKERY *VERSUS* LEGITIMATE MEDICINE.

THE recent trial of the case of HUNTER *versus* the *Pall-Mall Gazette* has done something—although, we fear, as yet, not very much—towards pointing out to the public both the limits which separate quackery from legitimate medicine and the line which ought to be drawn in the system of advertising, by every one aspiring to reputation in the Medical Profession. It is no unfair reflection upon the discernment and the attainments of the general mass of the public to assert that they know nothing, or next to nothing, of medicine itself, of the collateral sciences on which it is in great measure founded, or of the ethics which ought to form the code of those who practise it. It was very easy to perceive, by the demeanour of the jury who tried the HUNTER case, that they knew very little of the scientific questions at issue in the trial, and they did not seem to understand them even after the lucid evidence given by the witnesses for the defence; and it is notorious that the members of the legal profession, acute as they are in their own department, are, as a body, about as little informed on such matters as the outer world. From this observation we must except the Lord Chief Justice, Sir ALEXANDER COCKBURN, who, by the sagacity and intelligence of the questions he put, by his quick apprehension of the real points in dispute, and by his fair and generous appreciation of the merits of the scientific witnesses, dissipated the sophistical cobwebs which were wound round the case, and were calculated, and, no doubt, intended, to mystify and confuse the jury and the public.

On the other hand, many of the general newspapers, in their comments on the case, displayed the most profound ignorance of the very principles of chemistry, physiology, and pathology, and indeed many of them treated the whole subject as if these sciences had no foundation at all, and as if it was quite fair for any pretender, on the most shallow pretexts, to set up any silly theory of his own, the only criterion of merit being the success his pretensions might obtain. In the land of CAVENDISH and Sir HUMPHRY DAVY, it was apparently considered, even by several of the first-rate newspapers, to be quite an open question whether people might breathe an atmosphere of pure oxygen, not only without injury, but with positive benefit, although any one possessing the slightest knowledge of chemistry and physiology must know quite well that such an atmosphere is actually destructive by over-stimulation of the vital organs.

The outrageous system of advertising pursued by HUNTER is also treated very tenderly by the so-called leaders of public opinion, who seem to consider that medical men are mere traders, and that, as in other trades, those who pay most money for advertisements ought to obtain the greatest amount of celebrity. That the system was, for a time, wonderfully successful there can be no doubt, and it is quite evident that if any

enterprising pretender will undertake to do anything, however impossible, the columns of the *Times* and the *Daily Telegraph*, and the *Record*, &c., are all open to him for a consideration, and that they will proclaim his merits to an admiring and confiding public at so many pounds sterling a line in their *valuable* columns.

It is quite unnecessary for us, as medical writers, to point out the utter absurdity of Hunter's theory, if he really had any, as to the cure of tubercular disease, or to denounce the reckless extravagance, or rather perhaps the astounding boldness, with which he carried out his advertising scheme. We know that a man once advertised that he would jump into a quart bottle, and a number of people actually paid money to see him perform the feat, and there are so many instances of both individual and what we may call epidemic credulity in our own days, that we should not be surprised if people were persuaded (if only the discovery was duly advertised) that some modern alchemist had discovered the elixir of life, or the philosopher's stone. In proportion, too, as scepticism extends among our public writers as to the claims of real science, does an indefinite credulity lend itself to the empty fancies of the visionary, or the cunning devices of the ignorant but mercenary quack. Thus the honourable medical man who admits the difficulties of his art, is ridiculed as an obstruction, a bigot, or a fool, while the homœopathic quack, who pretends to cure all diseases by inert and infinitesimal globules, is regarded as the apostle of truth, and another who pretends to cure a disease by means which, if ever tried, would destroy the patient, is hailed as the herald announcing the dawn of a new medical philosophy.

ELECTION OF PROFESSOR OF BOTANY IN THE UNIVERSITY OF DUBLIN.

WE have much pleasure in announcing that Dr. ALEXANDER DICKSON of Edinburgh, has been chosen by the Provost and Senior Fellows of Trinity College, Dublin, to this important Professorship. Dr. DICKSON is a medical graduate of the University of Edinburgh, which has so often supplied Professors to the School of Physic in Ireland; he is a botanist of well known repute, and has been recommended for this Professorship by almost every professional botanist of note in Europe. We are glad to feel that our observations on this Professorship, in late numbers of this journal, have had their due weight, and that while in accordance with the letter and spirit of the School of Physic Act, a *bona fide* physician has been chosen to this post, yet, at the same time, that the demands of modern science have been fully met by appointing to a scientific professorship a scientific teacher, who gives every promise of reflecting credit on the choice of the Board of Trinity College, who have often shown themselves to be among the most liberal-minded corporation in the United Kingdom.

CHOLERA.

HEALTH OF LONDON.

It having been our duty for the last few months to furnish a weekly chronicle of the epidemic which has visited us, it affords us much gratification in the last number of the year to be able to report that the disease has now left us. A fortnight ago it was pronounced "extinct" by the Registrar-General, and as only three deaths have since been registered, we may confidently look forward to the new year.

Last week—the fiftieth week of the year—the deaths in London from all causes were eighty under the average—being only 1389, instead of 1469.

If spared a return of the epidemic next summer it will be abundantly proved that our sanitarians have not laboured in vain.

The following remarks of the Registrar-General sum up the facts, and deserve a place in our pages:—

"Two cases of cholera and 25 of diarrhœa were registered last week.

"A boiler-maker, aged 18 years, died on December 9 of bronchitis after cholera, at 17, Orchard-street, Woolwich.

"The son of a silk dyer, aged one year, died on December 10 of cholera (twenty-four hours), at 17, Fleet-street, Bethnal-green.

"Although the epidemic has subsided, isolated cases still demand the vigilant attention of the authorities. This is one of the lessons of the year; for, while cholera raged between the Tower, the Isle of Dogs, and Victoria Park—over the area traversed by the Blackwall Railway, and the Great Eastern Railway as far as Stratford and West Ham—among a population in uninterrupted communication, through lines of streets, the Regent's Canal, and the Thames, with the rest of London and the surrounding districts, to which many of the infected persons living in the east of London fled, the conflagration was strictly circumscribed within well-defined bounds. The fierceness of the disease extended thus far and no farther, although the movements of the people were as free as air. The utility of quarantine lines is so well known that their establishment was never proposed in London. The supply of impure water was at once arrested; the water engineers grew careful; and the sewage was now less inefficient than it ever had been before, for South London was drained; the health officers became vigilant; premonitory diarrhœa was treated; every case as it occurred was published to the world; and the cholera excreta were destroyed by carbolic acid and other disinfectants. The disease was communicated by contact with the poison in a few cases, but its general diffusion was stopped.

"This is the secret of the success of London in controlling an epidemic that during the year had been so fatal in continental cities.

"The annual rate of mortality last week was 24 per 1000 in London, 30 in Edinburgh, and 26 in Dublin; 20 in Bristol, 21 in Birmingham, 32 in Liverpool, 28 in Manchester, 27 in Salford, 29 in Sheffield, 24 in Leeds, 19 in Hull, 41 in Newcastle-upon-Tyne, and 31 in Glasgow.

"At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29.678 in. The mean temperature of the air in the week was 43.4 deg., which is 2.7 above the average of the same week in 50 years, (as determined by Mr. Glaisher). The mean of the highest temperature of the water of the Thames was 43.7 deg.; that of the lowest was 42.1 deg. The difference between the mean dew-point temperature and air temperature was 2.7 deg. The mean degree of humidity of the air was 90, complete saturation being represented by 100. Rain fell to the amount of 0.60 in. The general direction of the wind was south-west. According to a return furnished by the engineer of the Metropolitan Board of Works, the average daily quantity of sewage pumped into the river Thames at the southern outfall works, Crossness, was 208,033 cubic metres.*

* A cubic metre is equal in volume to 35.3174 cubic feet, or to 220.0967 imperial gallons. It is nearly equivalent to the old English tun of four hog-heads, or to 35.248 cubic feet. It is in general use on the Continent, and is a much better unit for measuring sewage or water supply than the gallon.

"The population, in 1866, of the six districts in the east of London and of the West Ham and Stratford sub-districts supplied from the Old Ford Reservoir, was 531,921; the deaths by cholera were 4104, being in the proportion of 77 deaths to 10,000 living. The population of London, exclusive of the six districts supplied from the Old Ford reservoir, was 2,566,882, and the number of deaths registered by cholera out of this population was only 1819, or in the proportion of seven deaths to 10,000 persons living."

Notes on Current Topics.

SCURVY IN THE MERCANTILE MARINE

WE are glad to hear that in consequence of the representations of Dr. Stone this subject is under the consideration of the Board of Trade. A correspondence has been going on in the *Times* in reference to this evil, and it is to be hoped that public opinion will enforce an attempt to eradicate it. We should rejoice to see the vendors of adulterated or diluted lime-juice condemned to the punishment they deserve. The strong arm of the law ought to be invoked for the protection of our sailors.

THE RIVER LEA.

THE Royal Commission on the Pollution of Rivers has commenced its inquiries into the condition of this stream. From what has already transpired of the proceedings, it would appear that the river is exposed to contamination at a much higher point than the "in-take" of any water company. We have no desire to anticipate the conclusions of the Commissioners, and therefore only direct the attention of our readers to the important evidence published by the daily papers.

TESTIMONIALS TO THE MEDICAL MEN AND NURSES ENGAGED IN THE CHOLERA EPIDEMIC.

AMONG the events of the week deserving of notice, we may name that some of the charities of London have been granting gratuities and testimonials to those of their officers whose services, during the recent epidemic of cholera, have been so frequently commended. On Monday the Committee of the City Dispensary voted a sum of ten guineas to the dispenser, in consideration of his extra work during the period referred to, and we believe that other similar institutions have previously expressed their thanks in the same manner. On Wednesday the Committee of the London Hospital presented various sums, amounting to nearly £1000, amongst their numerous officers. Such an appropriation of the funds of our charities might be very well extended, and we feel sure will meet with the approval of all subscribers. To nurses and medical men belongs a larger share of credit for the courage and devotion with which a national calamity was met, than to any other class; to them the whole community is indebted; it is, therefore, only just that to those who, in subordinate positions, discharged duties for which they can expect little honour, gratitude should be publicly expressed, accompanied by such pecuniary acknowledgment as the funds of the institutions where they laboured will permit.

YELLOW FEVER AT DEMARARA.

SOME sad accounts have been received respecting an outbreak of this epidemic at Demarara. On one side we hear of the garrison being decimated, on another we are told of about twenty soldiers having been carried off by the disease in a few days. Pending the arrival of further advices, we

can scarcely do other than refer to the want of sanitary arrangements in and around the barracks, as the most likely reason why the troops should die of an epidemic while the people in immediate proximity to them escaped.

With a burial-ground situated *inside* the cantonment, and, according to one account, "within twenty yards of the officers' quarters," we might anticipate a neglect of other precautions, and be prepared to learn that the dead are "buried within a few feet of the surface." As an excuse for this it has been alleged that water is found all over the colony at two or three feet from the surface. We are not, however, prepared to admit that our engineers could not drain the cantonment, nor are we disposed to acknowledge the propriety of keeping troops attacked by yellow fever within the focus of the disease, when no military reason can be assigned for doing so, and other healthy stations are so near. Had the energy so recklessly displayed at Southampton been transferred to the West Indies, we should have been more ready to acquiesce in its apparent wisdom.

CIVIC HONOURS.

WE hear that a testimonial is to be raised to the exertions of the Chairman of the Commissioners of Sewers. There is little doubt that this expression of the estimation in which his services have been held, by those well qualified to judge, is just. We are reminded, however, by the circumstances, that during the last summer an immense amount of unlooked for toil has been undergone by the able Medical Officer of the City—Dr. Letheby—and the inspectors under him. We are aware that those services are highly appreciated, but it has not yet come to our hearing that any public acknowledgment of them has been made. As the learned and indefatigable Officer of Health has to report to the Commissioners of Sewers, it seems natural to look to that body for some movement in this direction. Doubtless, not a few members of the Corporation of the City of London will be prepared to testify in a substantial manner their thanks to their sanitary officers. We should not allude to the topic, only that we have too often noticed how rapidly gratitude for sanitary benefits is likely to disappear. At the very least we trust some gratuity may be offered the inspectors, who have had an arduous task to fulfil. In this matter, *for once*, the charities are setting a worthy example.

YELLOW FEVER AND QUARANTINE.

THE Royal Mail Company's screw steamship *Tasmanian*, Captain E. M. Leeds, experienced a heavier visitation of yellow fever than either of the steamers that have preceded her. We extract from the *Times* the following particulars:

"There has been a total of 71 cases, 21 of which proved fatal, and 7 are now sick, 4 of whom are expected to die during the night. The last death occurred on the 13th. With one exception only, that of a medical man who was among the passengers, the attacks have, as heretofore, been confined to the crew, and in this instance no case has occurred among the engineers. The surgeon of the *Tasmanian*, Dr. R. Hudson, has fallen a victim to the dread disease, and his place has since been filled in attendance upon the sick by a third medical gentleman, who was fortunately on board. The following are the names of those who have died:—Dr. R. Hudson, surgeon; James Noyce, waiter; James Harper Henry Blake, Thomas Jones, and Enos Reeves, coal trimmers; Richard Holliday, Charles Diddams, and Benjamin Gettley, ordinary seamen; David Kenley, able seaman; Thomas Simeox, superintending barman of the Wye; Wm. Knight, dispensary boy; James McDonald, fireman; Wm. Heath, yeoman; John Sellis, engineer's servant; Henry Overton, baker's assistant; Charles Wilson, waiter; John H. Ball, barman; William Gosling, boatswain; and Thomas Mackenzie. Four of the deaths occurred before leaving St. Thomas, and the remainder on the voyage. The mails were

fumigated and landed in the docks a little before six o'clock, and the specie will undergo the same process in the morning. Dr. Wiblin, the medical superintendent of quarantine, ordered the healthy passengers to be immediately transferred to the company's steamer *Parana*, which is in the river prepared for the purpose, and the *Tasmanian* will proceed to the Motherbank early in the morning, when the healthy portion of the crew will be placed on board Her Majesty's ship *Æolus*, and the convalescents on board the quarantine hulk *Menelaus*."

The *Tasmanian* was detained several days in rigid quarantine off the Motherbank, and some of the circumstances have caused so much dissatisfaction that the Southampton Chamber of Commerce has opened communication with the Privy Council on the subject. A supplement to the *Gazette* of last Thursday directs every vessel from St. Thomas to come to anchor for the purpose of inspection.

LONDON METROPOLITAN BOARD OF WORKS.

THE report of this important body for 1865-6 now lies before us, and from it we gather a number of facts interesting to us, especially as guardians of the public health. The great undertaking of properly draining our overgrown metropolis rapidly approaches completion. On the south side of the river the work is already finished, and on the north side there only remains a portion in connection with the Thames embankment. By means of eighty-two square miles of sewers, one hundred and seventeen square miles of ground, inhabited by 2,800,000 persons, have been drained. This stupendous result has cost £4,200,000, and large as the sum seems we have already had evidence that it has been well expended. The first great result has been that the Thames, long condemned to be the main sewer of the capital, has been actually cleansed. Its waters have become so pure that various kinds of fish have returned in considerable quantities to the stream they had so long been abandoned. The more than Herculean task has been at last accomplished. Nevertheless, there remains yet something to do. Beyond the jurisdiction of the Metropolitan Board, the Upper Thames continues to receive the sewage of the towns on its banks, and until that also has been intercepted London will not enjoy the full benefit of the work already done. We commend this fact to our legislators, and sincerely trust the coming Session of Parliament will not be allowed to pass by without ample provision being made for the purification of the Upper Thames. As to the utilization of the sewage, of which so much has been said, we cannot do better than extract a passage relating to the concession for the sewage on the north side of the river:—

"The Board have now the satisfaction to report that the Company has been formed in conformity with the provisions of the Act, and that the sum of £25,000 has been deposited, in accordance with the terms of the agreement, as a guarantee for the due execution of their works, and that the Company have lately entered into a contract with the contractor, Mr. Webster, for the construction of the culverts and other works, which are now in active progress.

"Doubts having been expressed by Baron Liebig and other persons of scientific eminence as to the feasibility of Messrs. Napier and Hope's scheme, the Company have, during the past year, instituted a series of experiments to demonstrate the effects of the sewage on the sands to be reclaimed and acted upon; and, to afford facilities to persons who might wish to see some practical test of its merits, have entered into an arrangement with the Board to rent from them about ten acres of land adjacent to the northern outfall sewer at Barking, for the purpose of making a series of experiments. This land, which was in a very rough and uncultivated state has been covered with sand taken from the area proposed to be reclaimed from the sea, to the depth of about a foot, and on this rye-grass has been sown. This has been irrigated with sewage taken from the northern outfall sewer, and samples of the crops grown have been sent to the office of

the Board; and, judging from what has already been done, the theories of Baron Liebig and others are in no way borne out, and there appears to be no reason whatever to doubt the ultimate success of the larger undertaking to be carried out by the Company on the Maplin Sands."

The subject of ventilation of sewers has engaged much of the attention of the Board, but hitherto without result—though a hope is expressed of "devising a plan for meeting the object in view." A number of interesting experiments have been made by the engineer's department, which are thus related in the report:—

"Four classes of experiments have been made—

"1st. By the use of charcoal ventilating grates.

"2nd. By ventilation through chimney shafts and furnaces.

"3rd. By ventilation through pipes carried to the tops of buildings, &c.

"4th. By dilution of the sewage with water.

The observations made relative to the experiments instituted under the first head tend to show that, whilst there is no complaint of foul smell emanating through the gratings of the sewers, the charcoal appears to have the effect of diminishing the current of air through the ventilators, and of confining it to the sewers, so that if the system of ventilation by means of deodorizers were generally adopted, a great increase, both in the number and size of the ventilating shafts, would become necessary for the protection of men working in the sewers. The engineer, in conjunction with Dr. Miller, is at the present time conducting other experiments, in order more satisfactorily to test the efficiency of this mode of ventilation.

The ventilation by means of chimney-shafts and furnaces, so far as it has been practicable to test the system, has been satisfactory, but the experiments which have hitherto been made demonstrate that the establishment of a sufficient number of furnaces would involve an expenditure of £201,480 per annum for fuel, in addition to a cost of £460,000 for the construction of chimneys and furnaces, which would be far too expensive to enable the plan to be applied. There is reason to suppose, however, that it might be adopted with great advantage in localities where existing furnaces could be made available, the ventilation by means of the furnaces in Woolwich dockyard, to which reference was made in last year's report, having been so far attended with success. A further experiment is now in operation, with a view of ascertaining more definitely the cost and effect of sewer ventilation by means of the street gas burners.

"In carrying out experiments under the third head—namely, by ventilation through pipes conveyed to the tops of buildings, difficulty has been experienced in obtaining the permission of occupiers of houses to fix the pipes, in consequence of apprehension that foul gases, under certain atmospheric conditions, would descend the chimneys or enter the upper windows, and this fear might probably render a universal adoption of the plan impracticable.

"Calculations have been made with a view of ascertaining the practicability of adopting the plan of diluting the sewage, from which it appears that, in addition to the present supply, about forty-two millions of gallons of water daily would be necessary to carry out the plan, and, from communications with the several water companies, it does not appear that, with their present resources, such a large addition to the existing daily water supply could be obtained."

There are many other subjects in the report relating to the improvement of the metropolis, on which it is scarcely our province to enter. We cannot, however, pass by that of the preservation of open spaces. The Board deserve well of the public for the efforts they have made in this direction, and we cordially endorse the following statement, with which this part of the report concludes:—

"The Board cannot but express their earnest conviction of the growing importance of this subject in reference to the health of the metropolis. The absorption of open space by building operations in every direction within the metropolitan area, and the rapid increase of suburban towns and villages immediately adjacent, arising from the increased facilities for travelling afforded by the railway companies, call for constant attention on the part of the Board, and they

entertain the hope that the valuable information with regard to manorial and other rights which has been obtained by recent Committees of the House of Commons, may lead to the speedy passing of such measures as will secure to the present and future inhabitants of the metropolis, and its immediate neighbourhood, the perpetual use of open spaces and recreation grounds."

There is also some interesting information respecting the Petroleum Act, Dangerous Businesses, the Gas Acts, the Gardens in Towns Protection Act, the Houseless Poor Acts of 1864 and 1865, and numerous other subjects included in the operations of the Board of Works. Our space is too limited to dwell at length upon these, and we must therefore pass on to the appendix, in which we find the report of an inspection of the manure and chemical works in the neighbourhood of the Northern and Southern Outfalls, conducted by Dr. Letheby and the Chief Engineer, and which, after affording full information, thus concludes:—

"The results of these inspections are that large and very offensive operations are carried on in the neighbourhood of both the Northern and Southern Outfalls, and that the putrid and other vapours, emitted from the works, are diffused into the atmosphere, and wafted to a considerable distance.

"The two points which presented themselves to our consideration were: 1st—That these vapours, coming from the neighbourhood of the Outfalls, might very naturally be erroneously attributed to the sewage. And, 2nd—That the effluvia from the neighbouring factories may be a serious nuisance to the workpeople who will have to reside at the Drainage Outfalls. It is therefore of great importance that the character of these vapours should be identified, and that no false opinion should be entertained of them, as regards their connection with the sewage from the Outfalls.

"The locality of these manufactories appears to be as well suited for such operations as any within easy reach from London; but it is a serious question whether, in any locality, the manufacturers are not bound to use every precaution in the conduct of their works, so as to prevent, as far as possible, the escape of noxious effluvia into the atmosphere. In the present instances, there is no doubt that no precautions whatever are in use, but, on the contrary, the vapours evolved from the materials, in all stages of the manufacture, are permitted to escape freely into the atmosphere.

(Signed)

"HY. LETHEBY.

"J. W. BAZALGETTE."

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

Preliminary Examination in Arts.

November 24, 1866.

ARITHMETIC.—DR. RINGLAND.

1. Reduce 235,967 hours to weeks; and 71,871,900 seconds to hours.
2. Find the L. C. M. of 15, 16, 18, 20, 24, 25, 27, 30.
3. Find the value of $1\frac{1}{8} + 2\frac{3}{4} + 3\frac{1}{2} + 4\frac{3}{8}$.
4. Which is the greatest and which is the least of $\frac{3}{4}$, $\frac{2}{5}$, $\frac{3}{8}$?
5. Reduce 17 cwt. 3 qrs. 12 lbs. to a fraction of a ton.
6. Find 0.1751 of an acre.
7. Find the value of $2.117 \div .0073$.
8. Reduce to decimals $\frac{1}{16}$ of $\frac{1}{16}$; and $7\frac{1}{2}$ of $\frac{1}{22500}$.
9. What is the price of 1000 bags of Jamaica sugar, each weighing 1 cwt. 3 qrs. 10 lbs. @ 42s. per cwt.?
10. Calculate the rent of a farm of 55a. 3r. 19p., @ £1 11s. 6d. per acre.

EUCLID.—DR. RINGLAND.

1. Define accurately the following terms:—a *Right*, *Obtuse*, and *Acute* angle.
2. Prove that two straight lines cannot have a common segment; that is, they cannot coincide in part without coinciding altogether.

3. Prove and write out the construction accurately of the 24th proposition, First Book, which states that, "if two triangles have two sides of one respectively = to two sides of the other, but the angle in one greater than the angle in the other, the base which is opposite the greater angle is greater than that which is opposite the less.

4. By how much are the three interior angles of any triangle less than three right angles?

5. All the interior angles of any rectilinear figure together with four right angles are equal to twice as many right angles as the figure has sides.

6. The parallelograms about the diagonal of a square are squares.

7. On a given right line construct a square.

8. What connection have the 1st and 2nd propositions, Second Book, to one another?

9. What is the section of a line?

10. Construct a square equal to a given rectilinear figure.

ENGLISH HISTORY.—DR. BELCHER.

1. Dates of accession of the following Sovereigns:—William the Conqueror, Henry VIII., Charles I., William and Mary, and George III.

2. Remarkable events in the History of the British Constitution in the following reigns:—John, Henry VIII., James I., Charles II., James II., and George III.

3. Leading events in the careers of the following historical personages:—Richard I., Edward III., Richard III., Cardinal Wolsey, Earl of Strafford, and Warren Hastings.

4. Remarkable Statesmen in the Irish Parliament immediately preceding the Union.

5. Trace the descent of Queen Victoria from King James I.

6. In what reigns were the following statutes passed: Præmunire, Habeas Corpus, Act of Settlement, Emancipation, Parliamentary Reform?

7. What English King first assumed by Act of Parliament the title of King of Ireland; and in what year?

[MODERN GEOGRAPHY.—DR. BELCHER.

1. Name the colonial and foreign dependencies of the British Crown in Asia, Africa, and Australia.

2. Name the colonial possessions of Denmark in the East and West Indies.

3. The established religion and form of government in Sweden and Norway, Russia, Austria, Belgium, and Greece.

4. The chief coal and iron districts, and also the most remarkable places for hardware manufacture in England.

5. The chief towns of Portugal; and the principal sea-ports of Ireland and France.

6. Through what counties does the Great Southern and Western Railway run *en route* from Dublin to Cork?

7. Describe the most remarkable places passed by her Majesty's Mail *en route* from Kingstown to London; and also *en route* from Cork, by Newfoundland, to New York.

INJURIES OF THE KNEE-JOINT: EXTRACTION OF FOREIGN BODIES.

By P. C. LITTLE, F.R.C.S.I., &c.

Case I.—At 7 A.M. of the 17th September, I was called in attendance upon T. D., aged 35, a gentleman of good constitution, who had met with a sad accident under the following circumstances:—At ten o'clock of the previous night, when attempting to open a glass book-case, he lost his balance, his right knee passed with great force through the glass, he fell upon a shelf below, and was severely cut. Having sponged away the blood, bathed the knee with cold water, and dressed the wound with plaster, he retired to bed; but the pain and heat of the joint prevented him from resting for a moment, and I found him in great agony. The right knee was semi-flexed, and lying upon its outer side; the wound in it was situated at the lower and external margin of the patella; it was somewhat transverse; its inner extremity, which was on a plane considerably

lower than its outer, was in contact with the external edge of the ligamentum patellæ; it was nearly three quarters of an inch in length, and an eighth of an inch in breadth; its lips were red, slightly everted, and apparently sized together with a glistening straw-coloured matter, which also smeared the integuments of the leg, and resembled dried synovia.

The patient insisted there was no glass in the joint, and, therefore, no necessity for an exploration, which, however, after some reasoning he permitted. Flexing the limb, as I conceived it had been when the accident occurred, I opened the lips of the wound and carefully passed a blunt-pointed probe through them, when I was alarmed at finding free access to the joint, even to its posterior wall. After a few cautious movements of the instrument, I discovered a foreign body firmly fixed in the inner aspect of the external condyle of the femur. I left the probe *in situ* as a director, and immediately introducing a fine dressing forceps, I carefully grasped, and steadily drew forth, a large piece of glass, coated with dark coagulated blood. For its extraction considerable force was required, owing—first, to its having been embedded in the cartilage and bone; and, secondly, to the retraction of the integuments and condensed tissues of the knee. From the shock of the operation the patient grew faint; a little wine restored him, and he expressed himself greatly relieved. Blood flowed from the wound. Having extended the limb upon a splint, I secured it in that position by a few turns of a roller above the knee and ankle, and applied cold water dressing for the present, as a substitute for a cold evaporating lotion which I ordered. I also prescribed an aperient of calomel and jalap, and advised absolute rest of body and mind, low diet, no stimulants.

The fragment of glass was of the flatted kind. In shape it was an isosceles triangle; the base looked downwards and outwards relatively to the wound. It measured, from apex to base, more than an inch; the base exactly half an inch; thickness, a sixteenth of an inch. For the three following days the case seemed to progress satisfactorily, and my directions had been carefully attended to. The knee-joint presented no sign of inflammation; the lips of the wound had retracted; pain was only produced by firm pressure over the patella. The patient suffered merely from restlessness, and a dull pain in the back, from lying so long in bed, he thought.

On my morning visit of the 21st, sickness of stomach was superadded to the above, which gave me some anxiety. I prescribed an effervescent saline mixture. Ice to be added to the lotion and to the drinks.

At six P.M. I was hurriedly called to him, as he had fainted; he was retching violently; complained of intolerable pain of the head and back, and of unceasing sickness of stomach; the knee was scarcely any trouble to him; his face was flushed; pupils contracted; tongue thick and creamy; skin crisp and hot; pulse sharp and quick, 100. The wound appeared dry, tense, and tumefied; the joint and the anterior aspect of the thigh were very hot, red, and swollen, giving an erysipelatous character to the inflammation which had so suddenly burst forth; the normal figure of the joint was obliterated by the swelling, and slight pressure over the patella produced great pain; there were involuntary jerkings of the limb, and extreme depression of spirits.

I at once opened the wound, and allowed about a drachm of grumous blood and serum to run away. I then ordered the immediate application of twelve leeches to the joint, to be followed by hot poppy fomentations, and afterwards by warm poultices of bran and linseed meal. I prescribed, to be taken every second hour, two grains of the submuriate of mercury, with five of Dover's powder, slop diet, ice and iced drinks more frequently. The leeching was quickly succeeded by a mitigation of all the symptoms. The pulse had become soft, and had fallen to 80. In less than forty-eight hours the system was under the influence of the mercury, and the distressing conditions were removed. There was some supuration of the

wound, which, however, in about a fortnight healed in a kindly manner by constant poulticing, aided by rest and proper support to the joint. The subsequent treatment consisted in counter-irritation, bandaging, cold sponging of the knee, and general tonics. With a well-fitting elastic knee-cap, the patient was able to walk about in six weeks after the injury. The only bad consequence which remained after so fearful an accident was a weakness of the joint, which every day tended to strengthen.

Case 2.—November 12th, M. M., an active, healthy young lady, aged 24, was suffering much from the effects of an apparently trivial accident, which happened to her three days ago, in this way: Seeing a part of the carpet tossed she quickly knelt down to arrange it, when something like a pin pierced her right knee. She at once arose to examine the injured part, thinking the sharp substance was still adhering to it, but she only saw a drop of blood from a small puncture, and could feel no foreign body beneath; and as there was no pain she paid no further attention to the matter, until last evening when she experienced general uneasiness, with severe pain in the joint, which was aggravated on walking about. She poulticed the wound with bread and water during the night, but got little relief, and slept badly. I was therefore called in and found her in bed, with the limb fully extended, the position most easy to her. The knee was a good deal swollen and red, at its inner side, and pressure over the patella, especially downwards, elicited much pain. For the purpose of having a strong light, and more freedom of manipulation, I had the patient seated in a chair at a window, and her right foot placed on a foot-stool, the knee being flexed. By inspection I could scarcely determine where the puncture occurred. I was, however, enabled to do so with sufficient exactness by digital pressure, which I conceived excited more pain as I approached the seat of injury; and what was of still greater moment, I discovered below the patella at the inner edge of the ligament, and a little below the internal condyle of the tibia, a sharp abnormal elevation pointing downwards, which, upon closer and more prolonged examination, I was satisfied was a foreign body, and which I decided upon at once removing. To that end I pursued the following course:—The limb being flexed, I drew up on the patella the integument, and endeavoured to locate, and as much as possible to isolate the deep-seated prominence. With a Coxeter's lancet I then made an incision down upon the latter, which, by pressing all around, appeared as a dark spot at the bottom of the wound, and with a fine forceps I nipped and extracted the offending body, which proved to be the half of a tailor's needle, quite black and rusty. Perfect rest of the limb, and a cold evaporating lotion, subdued all inflammation in four days, after which the patient got up, wearing as a safeguard, for a week, a knee bandage. At the end of that time the joint was quite strong and well.

The foregoing are examples of a class of most serious accidents to joints, which, fortunately, seldom occur. The results which generally follow such injuries—amputation, resection, ankylosis, or death, indicate their dangerous character. We have all, at some time in our lives, experienced the pain and general uneasiness, and in severe cases the sickness of stomach and fainting, caused by a fall or a blow upon the knee; and we have remarked how slowly those disagreeable feelings have passed away. The explanation of such conditions may be found in the complicated structure of the joint; for, of all joints in the body, that of the knee is probably the most complex. It is composed of so many elements, so different in nature and functions, yet so harmonious among themselves, and forming such an admirable whole—an organism so intimately associated with our animal life, that it is not surprising the latter has been in some instances extinguished by the destruction of the former. Such cases demand all the judgment, skill, and energy of the practical surgeon, and open a fruitful field for the patient investigation of the pathologist.

Case 1 is noteworthy in many respects. It shows the

necessity of a precise knowledge of the history, and of a careful examination into the nature of such an injury. Had I adopted the patient's ideas as to the absence of glass from the joint, how incalculable might have been the mischief! Death itself might have followed. The incessant pain from the occurrence of the accident to my visiting the patient, in my mind pointed to a foreign body; and that such had penetrated the synovial cavity, appeared from the character of the pain—acute and enduring; and beyond doubt, from the extravasation of the synovia. The great sufferings created by the presence, even for a short time, of a bit of iron, or of rust, in the delicate structures of the eye, will afford some idea of the torment which must have resulted from a large piece of glass in the knee-joint—a region probably more sensitive, and more closely allied by sympathetic ties with the system generally. In the progress of this case the sympathies were so highly excited as to almost draw attention from the real source of disturbance and danger. There was nothing remarkable in the operative procedure for the removal of the offending substance, excepting the anxiety I felt lest I might fracture the glass in the joint. The admirable effects of local depletion, mercury, position, and support, were fully exemplified in the after management of the case.

Case 2 shows what peril may ensue upon a slight injury of the knee. Here we have synovitis resulting from a puncture of a needle. And how may this be explained? The synovial cavity may have extended below the point at which the needle entered, which is possible, as the membrane has been known to embrace the tubercle of the tibia; or the needle, in its upward course, may have penetrated first the semi-lunar cartilage, and then the synovial membrane; or, what is less likely, the inflammation may have attacked the latter by "contiguous sympathy."

The difficulty of detecting the foreign body was much lessened by flexing the limb—the position in which it was when the accident happened. Fear of puncturing the joint did not deter me from attempting to remove the exciting cause of the inflammation. Of two evils, I chose the less. The results of the treatment illustrate the propriety, in the less severe forms of synovitis, of first resorting to local remedies before we fall back upon that powerful, but often baneful auxiliary—mercury.

TO THE RIGHT HONOURABLE LORD NAAS, M.P.,
CHIEF SECRETARY FOR IRELAND.

(Copy.)

MY LORD,—We, the Medical Officers of Dispensaries and Workhouses in the counties of Sligo and Leitrim, desire to express our loyalty and fidelity to the Crown and Government, and our confidence in your Lordship to consult for the best interests of the State at this critical period. We therefore submit the claims of the medical officers of dispensaries and workhouses in Ireland for superannuation pensions, upon the following grounds, for your Lordship's consideration:—The long and expensive course of professional education required to qualify medical officers for their varied and responsible public duties—the prevention and treatment of disease, and the promotion of the public health in their respective districts—their time at all hours, even those of natural rest, being retained for a peremptory and perilous public service, which during pestilential periods cause a mortality amongst them greater than that in the most unhealthy dependencies of the British Crown, and renders their lives uninsurable except upon hazardous premiums.

The duties of resident Medical Officers of Lunatic Asylums in Ireland being required for only a few hundred inmates, for which they receive salaries of from £300 to over £400 a year and allowances, can be absent daily upon out-door private practice, and can retire upon full pay after twenty years such service, if declared infirm, and the medical officers of county gaols being also provided with superannuation pensions, tend to establish the claims of Poor-law Medical Officers for the same amount of retiring pension in return for their several years attendance upon thousands of a population in districts several miles in extent.

In England three-fourths of the population in Poor-law districts are comparatively rich and one-fourth poor; in Ireland three-fourths are poor and one-fourth comfortable; in England there are in consequence ample opportunities for private practice. The medical officers there are paid 1s. 6d. to 2s. 6d. for each vaccination, according to distance, by the Boards of Guardians; in Ireland the law allows only 1s. for each successful vaccination—no consideration for distance, as is the case in England. In Ireland the comparative poverty of the industrial classes, the indiscriminate issue of visiting tickets to every one who may apply, and the medical relief afforded to all without tickets, by a late sealed order, during epidemics of cholera, are calculated to prohibit any private practice on such occasions, and to prevent medical officers making any provision from such a source for old age and infirmity.

It seems detrimental to the public interests to continue infirm medical officers upon active duty, whilst to oblige them to resign after long and faithful services without superannuation pensions would be a severe measure—the most painful instances have occasionally occurred. May we therefore hope that in consideration for the interests of the country and the medical officers, as the expenses of registration of births, deaths, marriages, of vaccination, and of the sanitary measures, are more of general than of local Poor-law interest, and as half the Poor-law medical expenditure in England has been paid from the national treasury since 1846, that this measure will now be extended to Ireland, towards the payment of the salaries of the medical officers, and of superannuation pensions of full-pay for the few infirm medical officers who may survive twenty years such severe service, and half-pay for ten years service, if declared infirm.

When your Lordship considers the two pestilential kindred diseases—rinderpest and cholera—which afflicted bovine and human blood during the last eighteen months, and the comprehensive sanitary code enacted in consequence last session, your Lordship can perceive that the aid of medical and sanitary science and action is required to resist the ravages of both these diseases, and to apply that double comparative light to the consideration of both, which the medical profession can alone command, of which your Lordship, as Chairman of the Cattle Plague Committee, seemed so sensible.

As medical officers are generally regarded as the guardians of the public health, and through it of an important department of national wealth, we trust that through your Lordship's powerful influence, the principle of superannuation, now recognised by the State in every other department of the public service, may be extended to them.

For the Medical Officers,
W. R. HAMILTON, M.D., Chairman,
Medical Officer Carney District.
JAMES TUCKER, M.D., Secretary,
Medical Officer Sligo District.

Sligo, December, 1866.

Correspondence.

YELLOW FEVER AND QUARANTINE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—What has been so often written of that once powerful political thunderer of Printing House-square, applies with even more force to the past and present of its medical contemporary the *Lancet*.

Without doubt there are generally to be found men equal to the emergencies of their time, and that the journals in question were originated and raised to distinction by minds above mediocrity—possessed of more than the ordinary share of literary courage, and endowed with rare tact—their early career furnishes indisputable evidence.

Much to the honour of its founder be it spoken, the inauguration of the scientific journal was dependent on the never-tiring exertions of the son of a Somersetshire farmer—a fairer specimen of the offspring of the sturdy English yeoman could scarcely be conceived, and one which certainly contrasts strongly with the caricatures of him so often glibly depicted in some of our papers.

Whether the founder of the other leading organ sprung

from the same, or an equally respectable stock, I am uninforming, but that the mantles of both have fallen upon comparative pigmies, events are rapidly demonstrating, and that both organs are now trading on bygone reputations is beyond dispute—for upon what question, of late, has the thunderer shown itself in consonance with the intelligence of the age? That it has long lagged most miserably behind, in the competitive race, is the every day remark of its gradually declining circle of readers.

Its would-be scientific colleague shall have the advantage of making its own response.

The subject of the abuse of quarantine has been forced into a prominent position, and from the medical journal in question such scientific advice as the public might confidently act upon has been sought for in vain.

I am prepared to demonstrate by facts, endorsed by unquestionable authorities, that quarantine for yellow fever can only be regarded as an unmitigated senseless farce, and incapable of supplying a single well authenticated case in support of its efficacy.

The *Lancet* of December 1st, 1866, writes:—"The interval between the arrival of the *Tyne* and the release of the *Atrato* was sufficient for the Privy Council—influenced, no doubt, by the sharp criticisms to which the measures were subjected which had applied to the latter vessel—to arrive at a better knowledge of the requirements of a *stringent quarantine* against yellow fever. Ignorance cannot be pleaded for the blunders committed with respect to the *Atrato*." "That the precise teaching of the two outbreaks of yellow fever which *alone* (?) have occurred on European soil should have been set aside for the ignorant regulations of an exploded system of quarantine on these coasts, speaks on the one hand, little for the confidence of the Lords of the Council in the more advanced knowledge of medical science, or on the other, much for their yielding to that vague and almost instinctive but ill-regulated fear which possesses the uninitiated in presence of a deadly disorder." So far tolerably good—although wrong in fact; but this same *Lancet* in the same article finishes up by telling us that the successive introduction of yellow fever into one of our ports renders necessary, after the outbreak at Swansea, the revival of stringent measures of quarantine! Could advice have been more *obscure* and *illogical*? What can the Privy Council—leaving the public out of the question—think of such teaching? That any medical man could have written such trash is beyond credence.

Dr. Buchanan, in reference to the outbreak of yellow fever at Swansea, remarks "that there were twelve centres from whence the disease, if it had been communicable from person to person, had the opportunity of spreading, and that many of these localities were perfectly adapted for the spread of contagious diseases; yet, in no instance, out of all these, did a single person get yellow fever, or any disease simulating it."

In connection with the outbreak of yellow fever at St Nazaire, about which so much has been written, "the crew insisted on immediately leaving the pestiferous ship, and went to their homes. Inquiries were subsequently made respecting these men by the Commissary of Marine, who had given their permits, and it was ascertained that none of them had either transmitted the disease or had it themselves."

"When Lisbon, in 1857, was being so terribly scourged by yellow fever, thousands of its population fled far and wide into surrounding districts. Among those who thus fled, numbers were already incubating the disease, and of course fell with it in their respective places of refuge. In 182 cases of this description, the Portuguese Government caused inquiry to be made whether persons about the sick fugitives had shown any signs of the infection; and the answers were, that in no single case had this occurred."

If such facts, in addition to many more recently adduced in my pamphlet on the same subject, will not convince the Lords of the Privy Council and the public of the futility of quarantine, to say nothing of the costliness and cruelty of a system, based on antiquated opinions and ignorance, we may almost despair of the influence of any power which can be brought to bear on the question.

I am, sir, your's, faithfully,
EDWIN HEARNE,
M.B., Lond., F.R.C.S. Eng.

Southampton, December, 1866.

DISLOCATION OF THE THUMB.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Would you allow me to take advantage of the pages of your valuable journal to call the attention of the profession to a simple mode of reducing dislocations of the bones of the thumb—a species of accident which, although apparently trivial, have sometimes been the cause of much vexation to the surgeon from the difficulty experienced in restoring them to their normal position. It is now nearly two years since the plan I allude to first occurred to me, induced by the following circumstances:—

On Christmas evening, 1864, a gentleman called on me about eight o'clock, evidently suffering under very severe pain, and on putting a few questions to him I discovered that as he was walking in his drawing-room his foot caught in the carpet and he was thrown violently forward on the point of his thumb, which, as he told me, had become considerably shortened as the result of the accident. Upon examination I found that there was a dislocation of the second or ungual phalanx on the back of the first or proximal, with palpable reduction in length of the whole digit, accompanied with corresponding deformity. I immediately had recourse to the usual modes recommended for the relief of the accident in question, but having tried them all for some time a circumstance at last occurred which gave me the key as to the steps which should be adopted in the treatment of those cases. I saw, as each attempt at traction was made, that the anterior extremity of the first phalanx was tilted forwards—in fact removed from the dislocated bone, and here was the clue to the whole thing. I at once removed the cord and wetted chamois from the part, placed the injured thumb, with its anterior aspect on a table, keeping its edge close to the web between it (the thumb) and the index finger, and placing the points of my own thumbs behind the dislocated bone, pushed it forward, when it returned to its normal position without the least difficulty.

This case, satisfactory as far as it goes, still, in my mind, proves but very little, and I therefore looked forward very anxiously for a second opportunity for the purpose of testing the efficacy of the above method. This, after the lapse of some months, at length presented itself in the person of a young and very muscular labourer, with the form of accident not exactly similar to that of the preceding case, as in this instance the first or proximal phalanx was thrown on the back of the metacarpal bone. It had occurred late in the evening from a fall amongst a heap of loose stones. I saw him the following morning—some attempts having been made in the interval at its reduction, but without success—and, having put him in the same position as in the former instance, taking care, however, to support the head of the metacarpal bone well on the table, the dislocation was reduced with scarcely an appreciable effort.

Anxious still further to confirm the views stated above, I mentioned them to Mr. Stapleton, who listened to them with his usual courtesy, and promised to test their efficacy on the first opportunity that presented itself. The conversation took place on Saturday, the 24th of November, and on the following Monday morning, by a very remarkable coincidence, a woman presented herself at Jervis-street Hospital, with the last or ungual phalanx dislocated on the back of the first. Mr. Stapleton at once took advantage of the occurrence, and before the assembled class showed how easily it could be reduced by the means I have proposed.

Thanking this gentleman for the kind and generous manner in which he brought those facts under the notice of the last meeting of the Surgical Society, and trusting that the plan pointed out may yet be of some use to the practising surgeon, I am, sir, yours, &c.,

EDWARD LEDWICH, F.R.C.S.I.,
Surgeon to Mercer's Hospital.

HUNTER V. SHARPE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—The services rendered to the medical profession, and indeed to the public at large, by the *Pall-Mall Gazette* in their action, Hunter v. Sharpe, have been so important and so great that it behoves us, I think, to make some appropriate recognition of our obligation to that paper, which has indeed always and consistently advocated the claims of the profession, both individually and collectively.

I would therefore propose that a subscription list be opened, and that some suitable testimonial be purchased, expressive of our indebtedness and sympathy; or that the proceeds of the subscription be handed over to the proprietors of the *Pall-Mall Gazette*, to defray a portion of the legal expenses incurred by their denunciation of quackery.—I am, sir, yours truly,

HENRY WILSON.

OBSTETRICAL SOCIETY OF DUBLIN.

SATURDAY, DEC. 8TH.

MR. COLLIS communicated to the Society a new mode of operating in cases of harelip, for which he claimed the advantage of lessening the subsequent deformity. Mr. Collis objected to the ordinary operation on two grounds—first, that the true frenum was needlessly interfered with, and as a result the depth of the lip was seriously lessened; and secondly, that in this affection, characterised by deficiency of tissue, a still further diminution of tissue was made by the mode of baring the edges.

Mr. Collis's mode of operating is scarcely intelligible without diagrams, but it may be stated briefly that all the parings are utilized, so as to give greater thickness and depth to the lip, and to avoid the shortening of the cicatrix, which allows the tooth to be seen in consequence of the lip becoming notched or tucked up at the margin.

Medical News.

UNIVERSITY OF DUBLIN.—At the Winter Commencements, held on the 19th inst., the following, among other degrees, were conferred:—

M.B.—Charles Mayo (Fellow and M.A., New College, Oxford); Henry Fitzgibbon, James H. Usher, William D. Wilson, Thomas James, P. Holmes, Robert Edward Bredon, John Orton, Frederick Orton.

Chirurg. Magistri.—Thomas Waugh Belcher (*Stipendiis Condonatis*); Robert Edward Bredon.

M.A.—Charles Mayo (*ad Eundem Ocum.*); James H. Wharton.

M.D.—Charles Mayo.

B.A.—Robert Edward Bredon, Frederick Orton, John Orton, James H. Usher, William D. Wilson.

INSANE PAUPERS.—The annual statistics of pauper insanity just issued show that the number of insane paupers chargeable to the poor-rates in England and Wales on the 1st of January last was 39,918—namely, 29,674 lunatics and 10,244 idiots. The total number constituted 4.3 per cent. of the number of persons in receipt of relief, the lunatics being 3.2 per cent. and the idiots 1.1 per cent. Of 39,827 of the number, it is distinguished that 17,537 were males, and 22,390 females. A year before, on the 1st of January, 1865, the total number of paupers was above 5 per cent. greater, but the number of the insane was 1,320 less, constituting only 4 per cent. of the pauperism, the lunatics being only 2.9 per cent. and the idiots 1.1 per cent. The residences of 83,417 on the 1st January, 1865, were stated; and of 39,827 on the 1st January, 1866. 20,910 in 1865, and 21,986 in 1866, were in county of borough lunatic asylums; 1264 in 1865, and 1288 in 1866 were in registered hospitals or in licensed houses; 9756 in 1865, and 9973 in 1866 were in workhouses; 1041 in 1865, and only 993 in 1866 were in lodgings or boarded out; 5516 in 1865, and 5587 in 1866 were residing with relatives. There are a few returns not obtained, but they appear to relate only to the districts containing together about 1 in 200 of the population.

YELLOW FEVER AT DEMERARA.—The *Demerara Royal Gazette* of the 22nd ult. says:—"We regret to say that yellow fever has played sad havoc among the troops in the garrison, and particularly among the men of the 16th Regiment. On the 10 inst. such of them as survived and were capable of removal were shipped off to Barbadoes in a brigantine, as their only chance of safety. When the disease first made its appearance, had the troops been at once removed to Berbice, the Arabian Coast, or the neighbourhood of the penal settlement, the probability is that they would now have been enjoying good health, as it is a remarkable fact that, although yellow fever is among the shipping, not a single case had occurred in Georgetown or the neighbourhood, except at the garrison. Lieutenant

Pratt was attacked on the night of the 7th inst., died on the 10th, and was buried on the following afternoon with military honours. The unfortunate outbreak of yellow fever at the garrison has led to much discussion, not only in the Court of Policy, but out of doors. A committee was appointed to confer with the military authorities, but in consequence of the removal of the troops the action of the committee has been practically checked. "This is to be regretted, as it is very desirable that the cause of the prevalence of yellow fever at the garrison should, if possible, be ascertained, with a view to prevent the recurrence of the evil at some future day, and for the credit of the colony, which will probably suffer. When the great mortality among the troops comes to be reported in England every one will at once ascribe it to the climate, and British Guiana will be looked upon as a "soldier's grave," because no proper efforts have been made to investigate the matter. Some of the members of the Court of Policy were inclined to think that the fever was to be ascribed to the flushing of the garrison trenches with salt water, but, as it happens, the trenches in Kingston have for a long period of time, probably always, been flushed with salt water, and how comes it that although there are streets to the westward and south-westward of the garrison grounds, and the district is well populated, the fever has not touched a single victim in Kingston? The remarkable fact that, while the troops were more than decimated by yellow fever, not a solitary case occurred in Georgetown, not even among those who live in the immediate vicinity of the garrison, shows beyond all doubt that the mortality is owing, not to the climate, but to some special local cause which the military authorities have not taken the trouble to investigate, or have not had the keenness to discover. It is hard that the sickness should be ascribed to the climate, when there are strong facts to show that the climate has nothing to do with it, beyond this, perhaps, that European troops are brought from a country where the cold is severe to a warm country, instead of the change in their position being gradual. It is said that the garrison doctor objected at first to the men being removed to another locality; if so, much of the blame of the mortality which followed must be laid on his shoulders."

THE CATTLE PLAGUE IN HOLLAND.—Brussels, Dec. 14th.—The Belgian *Moniteur* publishes the following particulars concerning the cattle plague in Holland:—"The cattle plague appears to be making dreadful ravages among the cattle in Holland. The number of fatal cases do not cease to increase, and if the progress observed to have been made by the disease since the end of November continue, the losses of the Dutch farmers will soon exceed those of the English cattle owners at the time when the plague was most violent. According to the official reports the number of cases among cattle were for the weeks ending November 3rd, 1443; 10th, 1551; 17th, 1595; 27th, 3257; and Dec. 4, 162. The last number is more than double that which was recorded when the epidemic was at its worst in Dec., 1865, and everything tends to show that it does not indicate the greatest height of the disease. The cattle plague was especially virulent in the provinces of Utrecht and Southern and Northern Holland, but it has also shown itself in Friesland and Overijssel, and has latterly attacked many parishes of Guelderland and North Brabant. Belgium having such extended and frequent relations with Netherlands is especially menaced by these circumstances. She will only succeed in keeping herself free from contagion by never for a moment relaxing the most rigorous vigilance and circumspection. The authorities and farmers on the frontier especially ought never to lose sight of this line of conduct."
—*Reuter's Express.*

RATING OF SCHOOLS AND CHARITABLE INSTITUTIONS.—The Mayor of Birmingham last week convened a meeting in that town for the purpose of taking into consideration the alleged abolition by recent judicial decision of the exemption of schools and charities to assessment to the relief for poor, &c. There was a large attendance. His worship explained that the decision referred to was the one pronounced in the House of Lords in the appeal "Jones and others v. the Mersey Docks and Harbour Company." The legal adviser of the overseers has given an opinion that that decision fixed the law of the case, and the Mayor said if this was to be enforced it would be a new and oppressive tax, not only on the charities of the town, but of the United

Kingdom. The meeting was addressed by the Hon. and Rev. G. M. Yorke, and by several of the principal of the clergy and laity. Ultimately, the following resolutions were passed:—"That the assessment to the relief of the poor of schools supported either wholly or partially by voluntary subscriptions is most inexpedient, because it will seriously retard the spread of education, which is the most effectual remedy against improvidence and pauperism. "That hospitals and other charitable institutions of a similar character, the operations of which tend to diminish the poor-rates, ought to enjoy exemption from such rates, and to rate them would greatly diminish their efficiency in this respect; and, while the additional sum gained will be inappreciable to the ratepayers generally, it will subject that small section of them who support such charitable institutions to an increased and increasing burden, which is unfair and impolitic." "That the alleged abolition by judicial decision of the exemption which has been enjoyed for more than two centuries demands the immediate interference of the Legislature, and that a committee be formed for the purpose of procuring an Act to continue the former exemption, and of taking such other steps as may seem to them desirable." A committee was appointed for the purpose of taking such steps as may be deemed necessary to prevent the law referred to being enforced.

ADULTERATION OF FLOUR.—At the Southwell Petty Sessions in Nottinghamshire, on Friday, Mr. Joseph Marriott, a miller in a respectable position at Fiskerton, was convicted of selling flour adulterated with alum, and was fined £15 for the offence.—*Times.*

In the earlier impressions of our number for the 19th inst., in Dr. Stokes's address, the name of Dr. John Hughes was inadvertently omitted as the author of the paper on Morbus Addisonii; and also the name of Dr. Belcher as the author of one of the papers on Diphtheria.

Notices to Correspondents.

Communications to the London Editor should be addressed to 20, King William-street, Strand; to the Edinburgh Editor at Maclellan and Stewart's, South Bridge; and to the Dublin Editor, at 3, Lincoln-place.

Every MS. should bear the Name and Address of the Sender.

All Contributions are attentively considered, and unaccepted MSS. are returned on receipt of stamps for postage; but the Editors cannot be responsible for any accidental loss, nor can MSS. or replies be delivered on personal application.

Contributions should be *legibly* written, and only on one side of the paper.

When proofs are forwarded it is of the utmost importance that they should be corrected and returned without delay.

Communications respecting Hospital Reports should be addressed to "Editor of Hospital Reports Department," London, Edinburgh, and Dublin, respectively.

Dr. Fleming, Newtonianway.—The journal was not stopped for the reason you suppose, but delayed owing to our free issue to the entire profession.

Dr. Hadden, Clonakilty.—The account was sent before the order was received—a receipt will be forwarded. We have your communication for publication as soon as we can find space.

We have to apologise to our subscribers for delay in the receipt of their journal of the 19th. The issue of a free copy (20,000) to every member of the profession in the United Kingdom is an undertaking which can only be estimated with the knowledge that each copy has to go through twenty-seven different operations, and that our machinery has been occupied almost constantly night and day for the last week to meet the supply.

BOOKS, &c., RECEIVED.

Dr. Chambers on "The Indigestions." St. George's Hospital Reports, vol. 1.

Action of Medicines. By Dr. Headland. Fourth Edition. London: John Churchill and Sons.

Report of the Papers, &c., of the British Association for the Advancement of Science.

The Pill Book, including Quack Medicines. By Arnold J. Cooley, Esq. London: Robert Hardwicke, Piccadilly.

Proceedings and Reports from the Sanitary Committee of the Parish of Chelsea. London: Pike and Son, Chelsea.
